LMV710/LMV711/LMV715

Low Power, RRIO Operational Amplifiers with High Output Current Drive and Shutdown Option

General Description

The LMV710/LMV711/LMV715 are BiCMOS operational amplifiers with a CMOS input stage. These devices have greater than RR input common mode voltage range, rail-to-rail output and high output current drive. They offer a bandwidth of 5 MHz and a slew rate of 5 V/μs.

On the LMV711/LMV715, a separate shutdown pin can be used to disable the device and reduces the supply current to 0.2 μA (typical). They also feature a turn on time of less than 10 μs. It is an ideal solution for power sensitive applications, such as cellular phone, pager, palm computer, etc. In addition, once the LMV715 is in shutdown the output will be "Tri-stated".

The LMV710 is offered in the space saving 5-Pin SOT23 Tiny package. The LMV711/LMV715 are offered in the space saving 6-Pin SOT23 Tiny package.

The LMV710/LMV711/LMV715 are designed to meet the demands of low power, low cost, and small size required by cellular phones and similar battery powered portable electronics.

Features

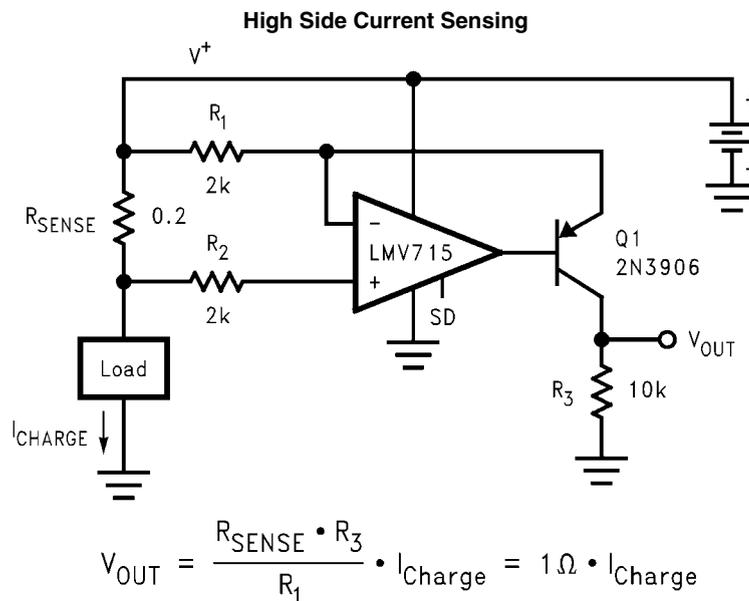

(For 5V supply, typical unless otherwise noted).

- Low offset voltage 3 mV, max
- Gain-bandwidth product 5 MHz, typ
- Slew rate 5 V/μs, typ
- Space saving packages 5-Pin and 6-Pin SOT23
- Turn on time from shutdown <10 μs
- Industrial temperature range -40°C to +85°C
- Supply current in shutdown mode 0.2 μA, typ
- Guaranteed 2.7V and 5V performance
- Unity gain stable
- Rail-to-rail input and output
- Capable of driving 600Ω load

Applications

- Wireless phones
- GSM/TDMA/CDMA power amp control
- AGC, RF power detector
- Temperature compensation
- Wireless LAN
- Bluetooth
- HomeRF

Typical Application

10132513

Absolute Maximum Ratings (Note 1)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

ESD Tolerance (Note 2)	
Machine Model	100V
Human Body Model	2000V
Differential Input Voltage	± Supply Voltage
Voltage at Input/Output Pin	(V ⁺) + 0.4V (V ⁻) - 0.4V
Supply Voltage (V ⁺ - V ⁻)	5.5V
Output Short Circuit to V ⁺	(Note 3)
Output Short Circuit to V ⁻	(Note 4)

Current at Input Pin	± 10 mA
Mounting Temp.

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is intended to be functional, but specific performance is not guaranteed. For guaranteed specifications and the test conditions, see the Electrical Characteristics.

Note 2: Human body model, 1.5 k Ω in series with 100 pF. Machine model, 0 Ω in series with 100 pF.

Note 3: Shorting circuit output to V^+ will adversely affect reliability.

Note 4: Shorting circuit output to V^- will adversely affect reliability.

Note 5: The maximum power dissipation is a function of $T_{J(MAX)}$, θ_{JA} , and T_A . The maximum allowable power dissipation at any ambient temperature is $P_D = (T_{J(MAX)} - T_A)/\theta_{JA}$. All numbers apply for packages soldered directly into a PC board.

Note 6: Typical values represent the most likely parametric norm.

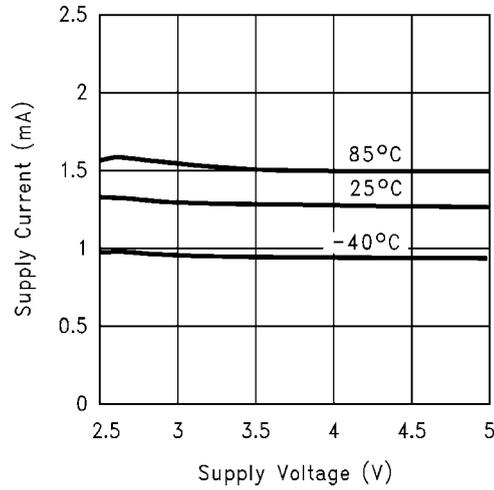

Note 7: All limits are guaranteed by testing or statistical analysis.

Note 8: Number specified is the slower of the positive and negative slew rates.

Typical Performance Characteristics

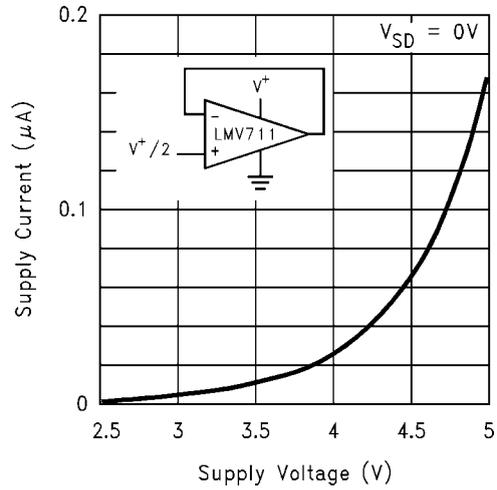

Unless otherwise specified, $V_S = +5V$, single supply, $T_A = 25^\circ C$.

Application Information

1.0 SUPPLY BYPASSING

The application circuits in this datasheet do not show the power supply connections and the associated bypass capacitors for simplification. When the circuits are built, it is always required to have bypass capacitors. Ceramic disc capacitors (0.1 μF) or solid tantalum (1 μF) with short leads, and located close to the IC are usually necessary to prevent interstage coupling through the power supply internal impedance. Inadequate bypassing will manifest itself by a low frequency oscillation or by high frequency instabilities. Sometimes, a 10 μF (or larger) capacitor is used to absorb low frequency variations and a smaller 0.1 μF disc is paralleled across it to prevent any high frequency feedback through the power supply lines.

2.0 SHUTDOWN MODE

The LMV711/LMV715 have a shutdown pin. To conserve battery life in portable applications, they can be disabled when the shutdown pin voltage is pulled low. For LMV711 during shutdown mode, the output stays at about 50 mV from the lower rail, and the current drawn from the power supply is 0.2 μA (typical). This makes the LMV711 an ideal solution for power sensitive applications. For the LMV715 during shutdown mode, the output will be "Tri-stated".

The shutdown pin should never be left unconnected. In applications where shutdown operation is not needed and the LMV711 or LMV715 is used, the shutdown pin should be connected to V^+ . Leaving the shutdown pin floating will result in an undefined operation mode and the device may oscillate between shutdown and active modes.

3.0 RAIL-TO-RAIL INPUT

The rail-to-rail input is achieved by using paralleled PMOS and NMOS differential input stages. (See Simplified Schematics in this datasheet). When the common mode input voltage changes from ground to the positive rail, the input stage goes through three modes. First, the NMOS pair is cutoff and the PMOS pair is active. At around 1.4V, both PMOS and NMOS pairs operate, and finally the PMOS pair is cutoff and NMOS pair is active. Since both input stages have their own offset voltage (V_{OS}), the offset of the amplifier becomes a function of the common-mode input voltage. See curves for V_{OS} vs. V_{CM} in curve section.

As shown in the curve, the V_{OS} has a crossover point at 1.4V above V^- . Proper design must be done in both DC and AC coupled applications to avoid problems. For large input signals that include the V_{OS} crossover point in their dynamic range, it will cause distortion in the output signal. One way to avoid such distortion is to keep the signal away from the crossover point. For example, in a unity gain buffer configuration and with $V_S = 5\text{V}$, a 3V peak-to-peak signal center at 2.5V will contain input-crossover distortion. To avoid this, the input signal should be centered at 3.5V instead. Another way to avoid large signal distortion is to use a gain of -1 circuit which avoids any voltage excursions at the input terminals of the amplifier. See *Figure 1*. In this circuit, the common mode DC voltage (V_{CM}) can be set at a level away from the V_{OS} crossover point.

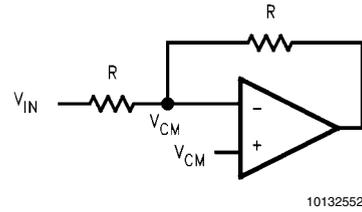

FIGURE 1.

When the input is a small signal and this small signal falls inside the V_{OS} transition range, the gain, CMRR and some other parameters will be degraded. To resolve this problem, the small signal should be placed such that it avoids the V_{OS} crossover point.

To achieve maximum output swing, the output should be biased at mid-supply. This is normally done by biasing the input at mid-supply. But with supply voltage range from 2V to 3.4V, the input of the op amp should not be biased at mid-supply because of the transition of the V_{OS} . *Figure 2* shows an example of how to get away from the V_{OS} crossover point and maintain a maximum swing with a 2.7V supply. *Figure 3* shows the waveforms of V_{IN} and V_{OUT} .

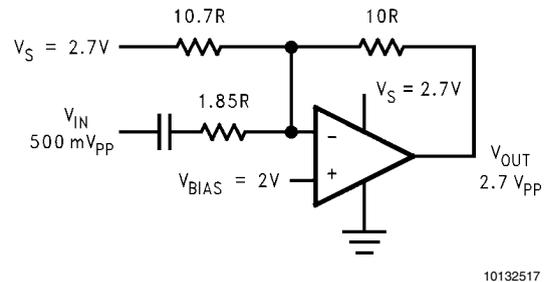

FIGURE 2.

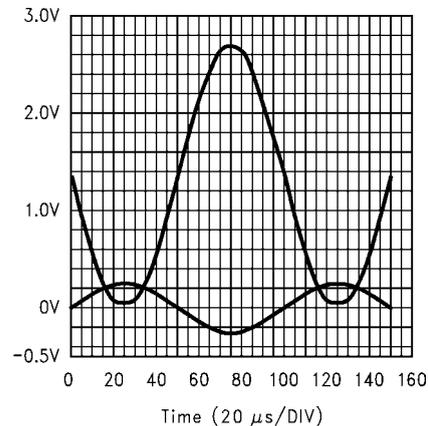

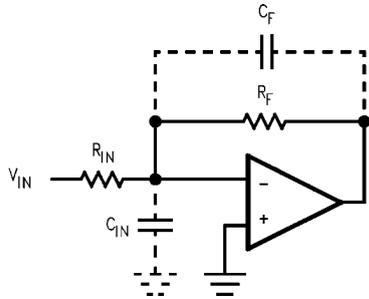

FIGURE 3.

The inputs can be driven 300 mV beyond the supply rails without causing phase reversal at the output. However, the inputs should not be allowed to exceed the maximum ratings.

4.0 COMPENSATION OF INPUT CAPACITANCE

In the application (Figure 4) where a large feedback resistor is used, the feedback resistor can react with the input capacitance of the op amp and introduce an additional pole to the close loop frequency response.

10132518

FIGURE 4. Cancelling the Effect of Input Capacitance

This pole occurs at frequency f_p , where

$$f_p = \frac{1}{2\pi(R_{IN} || R_F)C_{IN}}$$

Any stray capacitance due to external circuit board layout, any source capacitance from transducer or photodiode connected to the summing node will also be added to the input capacitance. If f_p is less than or close to the unity-gain bandwidth (5 MHz) of the op amp, the phase margin of the loop is reduced and can cause the system to be unstable.

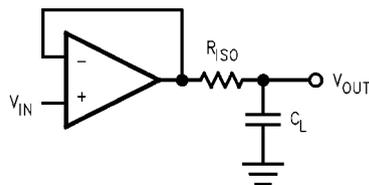

To avoid this problem, make sure that f_p occurs at least 2 octaves beyond the expected -3 dB frequency corner of the close loop frequency response. If not, a feedback capacitor C_F can be placed in parallel with R_F such that

$$\frac{1}{2\pi R_F C_F} = \frac{1}{2\pi(R_{IN} || R_F)(C_F + C_{IN})}$$

The paralleled R_F and C_F introduce a zero, which cancels the effect from the pole.

5.0 CAPACITIVE LOAD TOLERANCE

The LMV710/LMV711/ LMV715 can directly drive 200 pF in unity-gain without oscillation. The unity-gain follower is the most sensitive configuration to capacitive loading. Direct capacitive loading reduces the phase margin of amplifiers. The combination of the amplifier's output impedance and the capacitive load induces phase lag. This results in either an underdamped pulse response or oscillation. To drive a heavier capacitive load, circuit in Figure 5 can be used.

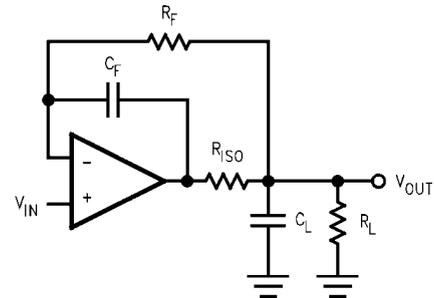

10132521

FIGURE 5. Indirectly Driving A Capacitive Load using Resistive Isolation

In Figure 5, the isolation resistor R_{ISO} and the load capacitor C_L form a pole to increase stability by adding more phase margin to the overall system. The desired performance depends on the value of R_{ISO} . The bigger the R_{ISO} resistor value, the more stable V_{OUT} will be. But the DC accuracy is not great when the R_{ISO} gets bigger. If there were a load resistor in Figure 5, the output would be voltage divided by R_{ISO} and the load resistor.

The circuit in Figure 6 is an improvement to the one in Figure 5 because it provides DC accuracy as well as AC stability. In this circuit, R_F provides the DC accuracy by using feed-forward techniques to connect V_{IN} to R_L . C_F and R_{ISO} serve to counteract the loss of phase margin by feeding the high frequency component of the output signal back to the amplifier's inverting input, thereby preserving phase margin in the overall feedback loop. Increased capacitive drive is possible by increasing the value of C_F . This in turn will slow down the pulse response.

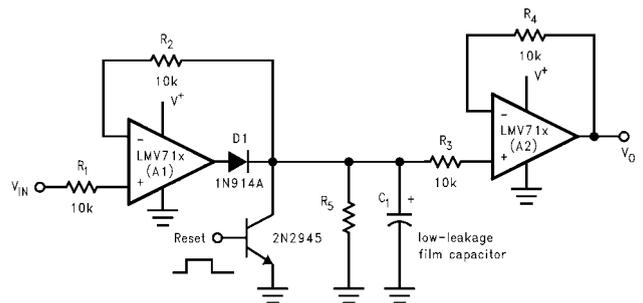

10132522

FIGURE 6. Indirectly Driving A Capacitive A Load with DC Accuracy

6.0 APPLICATION CIRCUITS

PEAK DETECTOR

Peak detectors are used in many applications, such as test equipment, measurement instrumentation, ultrasonic alarm systems, etc. Figure 7 shows the schematic diagram of a peak detector using LMV710 or LMV711 or LMV715. This peak detector basically consists of a clipper, a parallel RC network, and a voltage follower.

10132523

FIGURE 7. Peak Detector

The capacitor C_1 is first discharged by applying a positive pulse to the reset transistor. When a positive voltage V_{IN} is applied to the input, the input voltage is higher than the voltage across C_1 . The output of the op amp goes high and forward biases the diode D_1 . The capacitor C_1 is charged to V_{IN} . When the input becomes less than the current capacitor voltage, the output of the op amp A1 goes low and the diode

D_1 is reverse biased. This isolates the C_1 and leaves it with the charge equivalent to the peak of the input voltage. The follower prevents unintentional discharging of C_1 by loading from the following circuit.

R_5 and C_1 are properly selected so that the capacitor is charged rapidly to V_{IN} . During the holding period, the capacitor slowly discharge through C_1 , via leakage of the capacitor and the reverse-biased diode, or op amp bias currents. In any cases the discharging time constant is much larger than the charge time constant. And the capacitor can hold its voltage long enough to minimize the output ripple.

Resistors R_2 and R_3 limit the current into the inverting input of A1 and the non-inverting input of A2 when power is disconnected from the circuit. The discharging current from C_1 during power off may damage the input circuitry of the op amps.

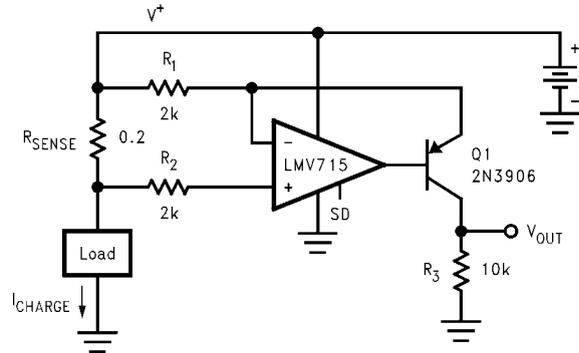

The peak detector can be reset by applying a positive pulse to the reset transistor. The charge on the capacitor is dumped into ground, and the detector is ready for another cycle.

The maximum input voltage to this detector should be less than $(V^+ - V_D)$, where V_D is the forward voltage drop of the diode. Otherwise, the input voltage should be scaled down before applying to the circuit.

HIGH SIDE CURRENT SENSING

The high side current sensing circuit (Figure 8) is commonly used in a battery charger to monitor charging current to pre-

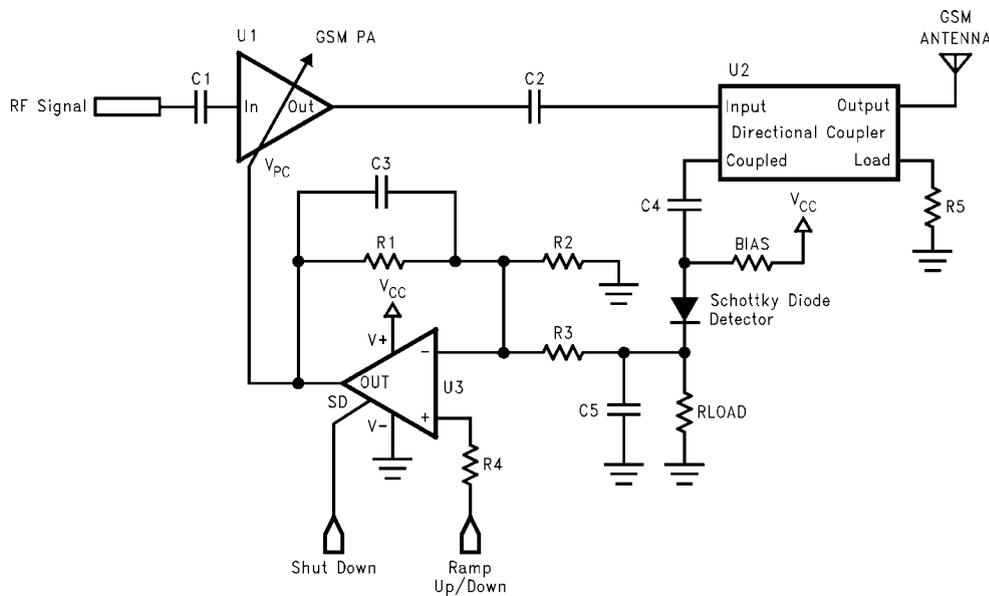

vent over-charging. A sense resistor R_{SENSE} is connected to the battery directly. This system requires an op amp with rail-to-rail input. The LMV710/LMV711/LMV715 are ideal for this application because its common mode input range can go beyond the positive rail.

$$V_{OUT} = \frac{R_{SENSE} \cdot R_3}{R_1} \cdot I_{Charge} = 1\Omega \cdot I_{Charge}$$

10132513

FIGURE 8. High Side Current Sensing

10132506

FIGURE 9. Typical of GSM P.A. Control Loop

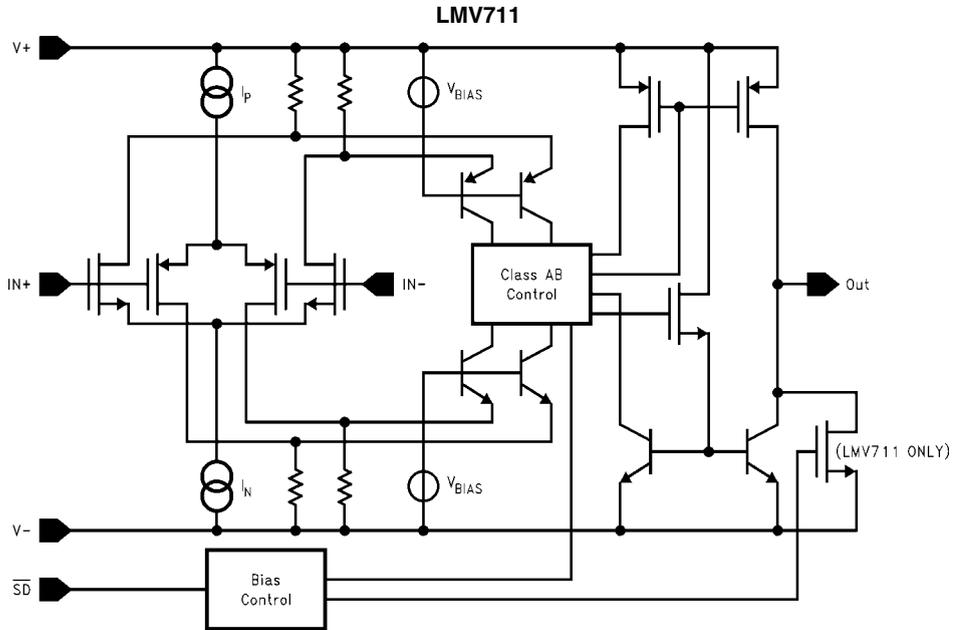

GSM POWER AMPLIFIER CONTROL LOOP

There are four critical sections in the GSM Power Amplifier Control Loop. The class-C R_F power amplifier provides amplification of the R_F signal. A directional coupler couples small amount of R_F energy from the output of the R_F P. A. to an envelope detector diode. The detector diode senses the signal level and rectifies it to a DC level to indicate the signal strength at the antenna. An op amp is used as an error amplifier to process the diode voltage and ramping voltage. This loop control the power amplifier gain via the op amp and forces the detector diode voltage and ramping voltage to be

equal. Power control is accomplished by changing the ramping voltage.

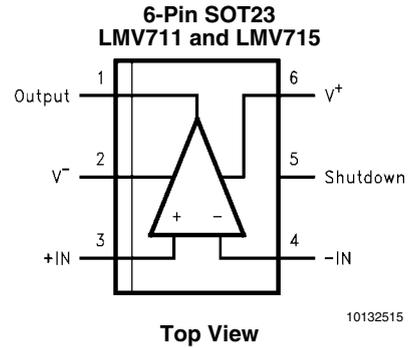

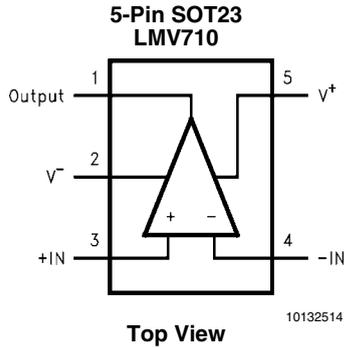

The LMV710/LMV711/LMV715 are well suited as an error amplifier in this application. The LMV711/LMV715 have an extra shutdown pin to switch the op amp to shutdown mode. In shutdown mode, the LMV711/LMV715 consume very low current. The LMV711 provides a ground voltage to the power amplifier control pin V_{PC} . Therefore, the power amplifier can be turned off to save battery life. The LMV715 output will be "tri-stated" when in shutdown.

TESTING AND OTHER QUALITY CONTROLS ARE USED TO THE EXTENT NATIONAL DEEMS NECESSARY TO SUPPORT NATIONAL'S PRODUCT WARRANTY. EXCEPT WHERE MANDATED BY GOVERNMENT REQUIREMENTS, TESTING OF ALL PARAMETERS OF EACH PRODUCT IS NOT NECESSARILY PERFORMED. NATIONAL ASSUMES NO LIABILITY FOR APPLICATIONS ASSISTANCE OR BUYER PRODUCT DESIGN. BUYERS ARE RESPONSIBLE FOR THEIR PRODUCTS AND APPLICATIONS USING NATIONAL COMPONENTS. PRIOR TO USING OR DISTRIBUTING ANY PRODUCTS THAT INCLUDE NATIONAL COMPONENTS, BUYERS SHOULD PROVIDE ADEQUATE DESIGN, TESTING AND OPERATING SAFEGUARDS.

EXCEPT AS PROVIDED IN NATIONAL'S TERMS AND CONDITIONS OF SALE FOR SUCH PRODUCTS, NATIONAL ASSUMES NO LIABILITY WHATSOEVER, AND NATIONAL DISCLAIMS ANY EXPRESS OR IMPLIED WARRANTY RELATING TO THE SALE AND/OR USE OF NATIONAL PRODUCTS INCLUDING LIABILITY OR WARRANTIES RELATING TO FITNESS FOR A PARTICULAR PURPOSE, MERCHANTABILITY, OR INFRINGEMENT OF ANY PATENT, COPYRIGHT OR OTHER INTELLECTUAL PROPERTY RIGHT.

LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS PRIOR WRITTEN APPROVAL OF THE CHIEF EXECUTIVE OFFICER AND GENERAL COUNSEL OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

Life support devices or systems are devices which (a) are intended for surgical implant into the body, or (b) support or sustain life and whose failure to perform when properly used in accordance with instructions for use provided in the labeling can be reasonably expected to result in a significant injury to the user. A critical component is any component in a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system or to affect its safety or effectiveness.
