

Description

The IPS2550 is a magnet-free, inductive position sensor IC that can be used for high-speed absolute position sensing in automotive, industrial, medical, and consumer applications. The IPS2550 uses the physical principle of eddy currents to detect the position of a simple metallic target that is moving above a set of coils, consisting of one transmitter coil and two receiver coils.

The three coils are typically printed as copper traces on a printed circuit board (PCB). They are arranged such that the transmitter coil induces a secondary voltage in the two receiver coils, which depends on the position of the metallic target above the coils.

A signal representative of the target's position over the coils is obtained by demodulating and processing the secondary voltages from the receiver coils. The target can be any kind of metal, such as aluminum, steel, or a PCB with a printed copper layer.

The IPS2550 provides two independent output interfaces:

- A high-speed analog interface providing position information in the form of demodulated analog sine/cosine raw data
- An I2C digital interface for diagnostics and programming

The IPS2550 operates at rotation speeds up to 600 000 RPM (relating to coil designs using 1 period per turn). An ultra-low propagation delay of 4µs provides high dynamic control for fast spinning motors.

The IPS2550 has been developed according to ISO26262 for implementation in safety-relevant systems up to ASIL C for a single IC and ASIL D for dual, redundant ICs. It is available in a 16-pin exposed pad TSSOP package and qualified for automotive use at -40°C to +160°C ambient temperature.

Available Support

Renesas provides reference designs that demonstrate IPS2550 rotary position sensing applications.

Typical Applications

- Rotor position detection for brushless DC motors; adaptable to any pole pair count
- Replacement of resolvers

Features

- Position sensing based on an inductive principle
- Cost-effective; no magnet required
- Immune to magnetic stray fields; no shielding required
- Suitable for harsh environments and extreme temperatures
- Differential and single-ended sine and cosine outputs
- Automatic gain control with programmable limits
- Nonvolatile user-configurable memory, programmable via I2C interface
- Programmable through analog or digital interface
- Single IC supports on-axis and off-axis rotation, linear motion, and arc motion sensing
- Adaptable to any full-scale angle range through coil design
- High accuracy: $\leq 0.1\%$ full scale (with ideal coils)
- Rotation sensing up to a 360° angle range
- Over-voltage and reverse-polarity protection: $\pm 18\text{V}$ on both supply and output pins
- Facilitates redundant design requirements
- Suitable for implementation in safety-related systems compliant to ISO26262 up to ASIL-C on a single IC and ASIL-D on dual ICs
- Fast diagnostic alarm via interrupt pin
- Wide operation temperature: -40°C up to +160°C
- Supply voltage programmable for $3.3\text{V} \pm 10\%$ or $5.0\text{V} \pm 10\%$
- Small 16-TSSOP exposed pad package (4.4mm × 5.0mm)

1. Pin Assignments

The IPS2550 is available in a 16-TSSOP 4.4mm × 5.0mm RoHS package with exposed pad RoHS package. It is qualified for an ambient temperature of -40°C to +160°C.

Figure 1. Pin Assignments for 16-TSSOP Package – Top View

2. Pin Descriptions

Table 1. Pin Descriptions

Pin Number	Name	Type	Description	
1	ADR_IRQN	Digital Input/Output	Address-select digital input for I2C interface address selection; push/pull interrupt output (programmable options, see Table 3). When used as I2C address-select input, use a pull-up or pull-down resistor $\geq 4k\Omega$ to select the I2C address.	
2	RX1	Analog Input	ASIL-C Configuration Mode (default) : receiver coil 1 (Sine, see Figure 2)	Compatibility Mode: receiver coil 1 (Sine, see Figure 3)
3	RX2		ASIL-C Configuration Mode (default): receiver coil 2 (Cosine, see Figure 2)	Compatibility Mode: receiver coil 1 (inverted sine, see Figure 3)
4	RX3		ASIL-C Configuration Mode (default): receiver coil 1 (inverted sine, see Figure 2)	Compatibility Mode: receiver coil 2 (Cosine, see Figure 3)
5	RX4		ASIL-C Configuration Mode (default): receiver coil 2 (inverted cosine, see Figure 2)	Compatibility Mode: receiver coil 2 (inverted cosine, see Figure 3)
6	TX1	Analog Input/Output	Connect the transmitter coil between the TX1 and TX2 pins. The resonant frequency is adjusted with capacitors C_{TX1} from TX1 to GND and C_{TX2} from TX2 to GND as shown in Figure 2 and Figure 3. C_{TX1} and C_{TX2} must have the same capacitance value. They can be calculated with Equation 3.	
7	TX2			
8	VDDA	Supply	Internal analog voltage supply. Connect a capacitor C_{VA} (see Table 5) to the GND pin.	
9	GND	Supply	Common ground connection.	

Pin Number	Name	Type	Description
10	VDD	Supply	External supply voltage. Connect two parallel capacitors C_{VD} (see Table 5) to the GND pin.
11	COSN	Analog Output	Buffered analog output; see Table 2.
12	COS_SDA	Analog Output, Digital I/O	Buffered analog output; digital I2C data input/output during Programming Mode; see Table 2.
13	SINN	Analog Output	Buffered analog output; see Table 2.
14	SIN_SCL	Analog Output, Digital Input	Buffered analog output; digital I2C clock input during Programming Mode; see Table 2.
15	SCL	Digital Input	Clock input for digital programming and diagnostic I2C interface. Connect a pull-up resistor for normal operation, see Table 13. If not used, connect SCL to GND.
16	SDA	Digital Input/Output	Open drain bi-directional data I/O line for digital programming and diagnostic I2C interface. Connect a pull-up resistor for normal operation, see Table 13. If not used, terminate using a pull-up or pull-down resistor $\geq 4.7k\Omega$.
	Exposed Pad	Heat sink	Heat sink only. It can be connected with short, direct connection to GND (pin #9), or left unconnected. Refer to Figure 4 for details. Do not connect the exposed pad to any other potential than GND.

Table 2. Output Configuration

Pin (See Figure 1)		Output Depending on Mode			Diagnostic State, Program Options			
Pin Number	Pin Name	Analog Differential	Analog Single-Ended	Programming	Disabled	Mode1	Mode2	Mode3
14	SIN_SCL	SIN	SIN	SCL	SIN	SIN	Hi-Z	Hi-Z
13	SINN	SINN	REF	Not used	SINN	Hi-Z	SINN	Hi-Z
12	COS_SDA	COS	COS	SDA	COS	COS	Hi-Z	Hi-Z
11	COSN	COSN	REF	Not used	COSN	Hi-Z	COSN	Hi-Z

[a] Abbreviations used in Table 2:

SIN: Sine channel output, bias voltage = $VDD/2$

SIN: Inverted sine channel output, bias voltage = $VDD/2$

COS: Cosine channel output, bias voltage = $VDD/2$

COSN: Inverted cosine channel output, bias voltage = $VDD/2$

REF: DC output bias voltage, $VDD/2$

SCL: Serial clock input for I2C programming

SDA: Serial bi-directional data I/O port for I2C programming

Hi-Z: Output is high ohmic; diagnostics are indicated by external pull-up or pull-down resistors

Table 3. Digital Interface Configuration

Pin (See Figure 1)		Input/Output Depending on Interface Mode ^[a]	
TSSOP Pin Number	Pin Name	I2C with Address Select	I2C with Interrupt
16	SDA	SDA	
15	SCL	SCL	
1	ADR_IRQN	ADR	IRQN

[a] Abbreviations used in Table 3:

ADR_IRQN: Combined address select input and interrupt output

ADR: Hardware address-select input for I2C Mode (two address options, depending on digital input level at the ADR_IRQN pin)

SDA: Serial bi-directional data I/O port for I2C Modes

SCL: Serial clock input for I2C Modes

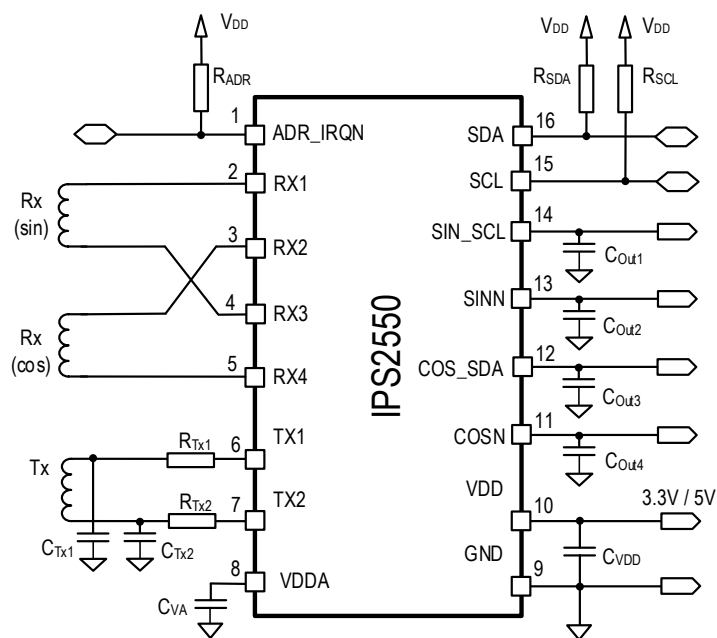

IRQN: Interrupt output

3. Receiver Coil Connection Options

The IPS2550 can be configured in two user-programmable modes related to the connection of the receiver coils:

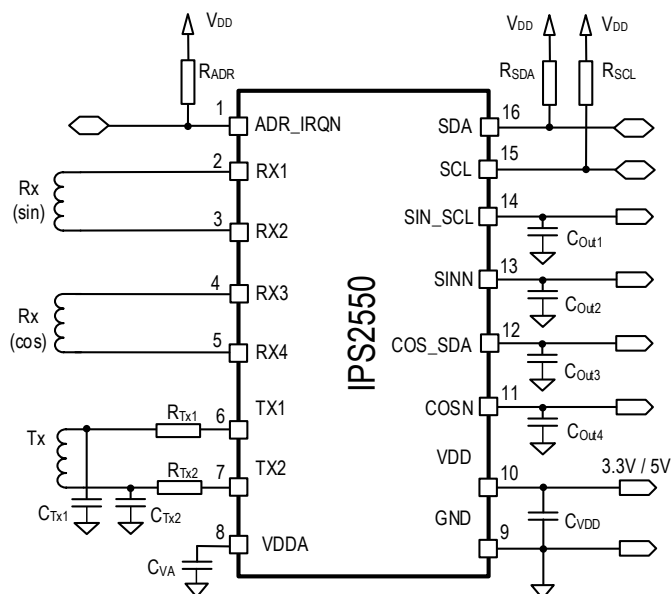

- The ASIL-C Configuration Mode (default) improves the failure detection rate of the chip because it avoids a short circuit of any receiver coil by a short between two neighboring pins.
- The Compatibility Mode (programming option) provides pin-to-pin compatibility with the IPS2200 inductive sensor IC.

Figure 2. LC Oscillator Connection in ASIL-C Configuration with Split TX Capacitors

Configuration in ASIL-C mode with split capacitors $C_{Tx1} = C_{Tx2}$, Tx coil series resistors $R_{Tx1} = R_{Tx2}$ and Output capacitors $C_{Out1} = C_{Out2} = C_{Out3} = C_{Out4}$ for improved EMC performance.

Figure 3. LC Oscillator Connection in Compatibility Mode Configuration with Split TX Capacitors

Configuration in compatibility mode with split capacitors $C_{Tx1} = C_{Tx2}$, Tx coil series resistors $R_{Tx1} = R_{Tx2}$ and Output capacitors $C_{Out1} = C_{Out2} = C_{Out3} = C_{Out4}$ for improved EMC performance.

The oscillator frequency is determined by the values of coil L and capacitors C_{Tx1} and C_{Tx2} as the following:

Oscillator frequency:

$$f_{TX} = \frac{1}{2\pi \sqrt{\frac{L \times C_{Tx1} \times C_{Tx2}}{C_{Tx1} + C_{Tx2}}}}$$

Equation 1

For $C_{Tx1} = C_{Tx2}$:

$$f_{TX} = \frac{1}{2\pi \sqrt{L \frac{C_{Tx1}}{2}}}$$

Equation 2

$$C_{Tx1} = C_{Tx2} = \frac{2}{L(2\pi f_{TX})^2}$$

Equation 3

Where:

f_{TX} = Oscillator frequency in MHz

L = Coil impedance in μ Henry

C_{Tx1} , C_{Tx2} = Capacitance in μ Farad

Note: $R_{Tx1} = R_{Tx2} = 220\Omega$ (typical)

4. Absolute Maximum Ratings

The absolute maximum ratings are stress ratings only. Stresses greater than those listed below can cause permanent damage to the device. Functional operation of the IPS2550 at the absolute maximum ratings is not implied. Exposure to absolute maximum rating conditions could affect device reliability.

All voltage levels refer to GND.

Table 4. Absolute Maximum Ratings

Symbol	Parameter	Conditions	Minimum	Maximum	Units
V_{VDDmax}	External supply voltage	Continuous	-18	18	V
V_{OUT}	SIN_SCL, SINN_COS_SDA and COSN output voltage	Continuous	-18	18	V
V_{RX1}	Receiver coil pin: RX1		-12	12	V
V_{RX2}	Receiver coil pin: RX2				
V_{RX3}	Receiver coil pin: RX3				
V_{RX4}	Receiver coil pin: RX4				
$V_{DIGITAL}$	Digital IO pins: SCL, SDA, ADR_IRQN		-0.3	VDD+0.3	V
V_{Tx1_2}	Transmitter pins, TX1, TX2		-0.3	5.6	V
$V_{VDDAmax}$	VDDA internal LDO output	VDDA is internally regulated with external capacitor to GND. No other connection to external voltages.	Refer to V_{VDDA} , Table 5		V

5. Operating Conditions

Conditions: VDD = 5V \pm 10%, T_{AMB} = -40°C to +160°C, unless otherwise noted.

Table 5. Operating Conditions

Note: See important notes at the end of the table.

Symbol	Parameter	Conditions	Minimum	Typical	Maximum	Units
T _{AMB_TSSOP}	Ambient temperature	16-TSSOP package with exposed pad	-40		160 ¹	°C
T _J	Junction temperature		-40		165	°C
T _{STOR}	Storage temperature	Unmounted units must be limited to 10 hours at temperatures above 125°C	-55		160	°C
R _{THJA_TSSOP}	Thermal resistance junction to ambient: 16-TSSOP package with exposed pad. Velocity = 0m/s JEDEC MO-153.	Copper ground planes under exposed pad on 4 layer PCB, 3x3 thermal vias between layers.		35.48		K/W
		Copper ground planes under exposed pad on 2 layer PCB, 3x3 thermal vias between layers.		39.96		

¹ Ambient temperature above 155°C limited to 120 hours over lifetime.

Symbol	Parameter	Conditions	Minimum	Typical	Maximum	Units
		Without PCB ground plane under exposed pad.		61.26		
R _{THJC_TSSOP}	Thermal resistance junction to case	Junction to bottom of package		6.42		K/W
t _{pup}	Start-up time	Power-on reset (POR) to valid output signal			5	ms
V _{EL}	Input rotational velocity, Electrical speed; sine or cosine periods	Electrical revolutions per minute			600 000	rpm
		Input frequency			10	kHz
V _{VDDA_TH_H}	Power-on reset (POR), high threshold	The device is activated when VDDA increases above this threshold			2.49	V
V _{VDDA_TH_L}	Power-on reset, low threshold	The device is deactivated when VDDA decreases below this threshold	2.08			V
VDDA _{POR_HYST}	Power-on reset hysteresis	At VDDA pins		110		mV
I _{VDDA}	VDDA short circuit current limitation	VDDA must be connected to a capacitor C _{VA} . No other external load allowed at this pin.	40		85	mA
I _{CC}	Current consumption	Without coils, no load	5		12	mA
		Programmable transmitter coil drive current (depending on inductance of the transmitter coil)	For values, refer to Table 8.			mA
C _{VA}	Capacitor from VDDA pin to GND			100		nF
C _{VDD}	Capacitor from VDD pin to GND	Nominal value	70			nF
INL _{uv3V}	Accuracy, 3.3V Mode, VDD= under-voltage alarm level to 3.0V	With ideal sinusoidal input signals, 150mV _{pk-pk} Differential output mode, Transmitter frequency = 3.5MHz AGC = on Channel swapping = 0ff			±0.2	% FS [a]
INL _{3V}	Accuracy, 3.3V Mode, VDD= 3.0 to 3.6V				±0.1	% FS
INL _{ov3V}	Accuracy, 3.3V Mode, VDD= 3.6V to over-voltage alarm level				±0.2	% FS
INL _{uv5V}	Accuracy, 5V Mode, VDD= under-voltage alarm level to 4.5V				±0.2	% FS
INL _{5V}	Accuracy, 5.0V Mode, VDD= 4.5 to 5.5V				±0.1	% FS
INL _{ov5V}	Accuracy, 5.0V Mode, VDD= 5.5V to over-voltage alarm level				±0.2	% FS

[a] % FS = percent of full scale = accuracy in % per period, where 100% is the angle range of one electrical period.

For rotary multi-period designs, one electrical period = 360° (one full turn) divided by the number of periods per turn, see examples in section 20.

6. Ambient Temperature Range

The minimum ambient temperature for the IPS2550 is -40°C.

The maximum ambient temperature depends on the following factors:

- The maximum junction temperature, see Table 5 for details.
- The supply current. The total power consumption of the chip depends on the supply voltage, the internal supply current, and the user programmable transmitter coil current. The programmable transmitter coil current is shown in Table 8 and the internal circuit current consumption is shown in Table 5.
- The minimum usable coil current in a given application. Typically, smaller coils require more transmitter coil current and larger coils can operate with less coil current. Typical coil designs in the range of 25mm to 30mm coil diameter can require approximately 3mA to 5mA coil current, respectively around 12mA to 14mA supply current. The IPS2550 can drive as high as 20mA of transmitter coil current.
- The temperature range of the supplier part qualification. The IPS2550 is qualified for -40°C to +160°C ambient temperature.
- The thermal resistance of the package in combination with a copper ground plane area on the PCB.

The maximum supply current at VDD = 5.5V versus the ambient temperature with different PCB layers and no airflow cooling is shown in the circled areas of Figure 4. For example, the maximum supply current (internal current + transmitter coil current) at $T_{\text{ambient}} = 160^{\circ}\text{C}$ for a PCB with copper ground plane under the exposed pad is 25.6mA for a 4-layer PCB and 22.8mA for a 2-layer PCB. The ground plane is assumed having minimum the same rectangular area as the exposed pad and copied to all layers with a 3x3 array of interconnect vias between each layer.

Note: ignore the small half circles extended at each short side of the exposed pad on the package drawing at the end of this document, they do not need to be copied to the PCB ground plane.

Without copper ground plane(s) under the exposed pad, the maximum current consumption at 160°C ambient temperature is 14.8mA. If the maximum ambient temperature is less than 155°C and the maximum current consumption is below 29.7mA, no PCB ground planes are needed. If the maximum supply current is below 18mA, no PCB ground planes are needed up to an ambient temperature of 159°C

Figure 4. Maximum Supply Current vs Ambient Temperature, with and without Ground Plane

7. Electrical Characteristics

The following electrical specifications are valid for the operating conditions as specified in Table 5: (T_{AMB} is -40°C to 160°C).

Table 6. IPS2550 Electrical Characteristics, 3.3V Mode

Symbol	Parameter	Conditions	Minimum	Typical	Maximum	Units
VDD ₃	Supply voltage		3.0	3.3	3.6	V
V3 _{OV} R	Over-voltage detection, VDD rising	An over-voltage alarm is created if VDD rises above this limit	3.7	3.86	4.1	V
V3 _{OV} F	Over-voltage detection, VDD falling	An over-voltage alarm is cleared if VDD falls below this limit	3.65	3.79	4.0	V
V3 _{OV} H	Over-voltage detection hysteresis			70		mV
V3 _{UV} R	Under-voltage detection, VDD falling	An under-voltage alarm is created if VDD falls below this limit	2.65	2.75	2.90	V
V3 _{UV} F	Under-voltage detection, VDD rising	An under-voltage alarm is cleared if VDD rises above this limit	2.70	2.85	3.00	V
V3 _{UV} H	Under-voltage detection hysteresis			100		mV
VDDA ₃	Analog supply voltage	Internally regulated. Connect capacitor C _{VA} = 100nF between VDDA and GND (see Table 5)	2.85	3.0	3.1	V
V3VDDA _{UV} F	VDDA under-voltage detection	An under-voltage alarm is created if VDDA falls below these limits.	2.59		2.80	V
V3VDDA _{UV} R	VDDA under-voltage detection	An under-voltage alarm is cleared if VDDA rises above these limits.	2.63		2.85	V
V3VDDA _{UV} H	VDDA Under-voltage detection hysteresis			45		mV

Table 7. IPS2550 Electrical Characteristics, 5.0V Mode

Symbol	Parameter	Conditions	Minimum	Typical	Maximum	Units
VDD ₅	Supply voltage		4.5	5.0	5.5	V
V5 _{OV} R	Over-voltage detection, VDD rising	An over-voltage alarm is created if VDD rises above this limit	5.60	5.84	6.10	V
V5 _{OV} F	Over-voltage detection, VDD falling	An over-voltage alarm is cleared if VDD falls below this limit	5.55	5.76	6.05	V
V5 _{OV} H	Over-voltage detection hysteresis			80		mV
V5 _{UV} R	Under-voltage detection, VDD falling	An under-voltage alarm is created if VDD falls below this limit	4.10	4.33	4.45	V
V5 _{UV} F	Under-voltage detection, VDD rising	An under-voltage alarm is cleared if VDD rises above this limit	4.20	4.40	4.49	V
V5 _{UV} H	Under-voltage detection hysteresis			70		mV

Symbol	Parameter	Conditions	Minimum	Typical	Maximum	Units
VDDA ₅	Analog supply voltage	Internally regulated. Connect a capacitor C _{VA} = 100nF between VDDA and GND (see Table 5)	3.9	4.0	4.1	V
V5VDDA _{UVF}	VDDA under-voltage detection	A VDDA under-voltage alarm is triggered when VDDA falls below these limits.	3.50		3.79	V
V5VDDA _{UVRr}	VDDA under-voltage detection	A VDDA under-voltage alarm is cleared if VDDA rises above these limits.	3.60		3.87	V
V5VDDA _{UVH}	VDDA Under-voltage detection hysteresis			65		mV

Table 8. LC Oscillator Specifications

Symbol	Parameter	Conditions	Minimum	Typical	Maximum	Units
R _{P,eq}	Equivalent parallel resistance of the LC resonant circuit	See Equation 4	250			Ω
f _{LC}	Excitation frequency	LC oscillator frequency is determined by external components L and C.	2.0		5.6	MHz
V _{TX_P}	LC oscillator amplitude	Peak-to-peak voltage; pins TX1 vs. TX2; all modes. Adjustable by coil current.		6	11	V _{pp}
I _{LC}	Programmable transmitter coil drive current	Equivalent DC current. Programmable, depending on transmitter coil inductance.	0	3	20	mA
R _{TX1} , R _{TX2}	TX Series resistor	For reduced EMC emission		22		Ohm

Figure 5. Parallel Resonator Circuit

The equivalent parallel resistance R_{Peq} of the LC oscillator can be calculated using Equation 4. It defines the minimum loss resistance that the oscillator can drive for safe operation.

Note: for improved EMC performance, it is recommended to split capacitor C into two equal capacitors with double capacitance, connected to GND: $C_{TX1} = C_{TX2} = 2C$. See also Figure 2 and Figure 3 for further details.

$$R_{Peq} = \frac{1}{R_S} \times \frac{L}{C}$$

Equation 4

Where

- R_{Peq} Equivalent parallel resistance of the LC oscillator.
- R_S Serial resistance of the transmitter coil at the transmitter frequency.
- L Coil reactance at the resonant frequency.
- C Capacitance of the parallel capacitor CT.

Note that the capacitor losses are not included in the equation, since in case of C0G or NP0 ceramics they can be neglected.

Table 9. Coil Receiver Front-End Specifications

Symbol	Parameter	Conditions	Minimum	Typical	Maximum	Units
V_{RX}	Receiver coil amplitude.	Input signal full range to maintain AGC target levels: 3.0V p-p AGC target, gain boost bit disabled	25		1500	mV _{pp}
		Input signal full range to maintain AGC target levels: 3.0V p-p AGC target, gain boost bit enabled	13		780	
		Input signal full range to maintain AGC target levels: 1.8V p-p AGC target, gain boost bit disabled	15		920	
		Input signal full range to maintain AGC target levels: 1.8V p-p AGC target, gain boost bit enabled	8		470	
A_{IN_mm}	Maximum amplitude mismatch correction	Programmable individual gain mismatch correction of Receiver coil signals (SIN and COS)	13		20	%
	Amplitude mismatch step size		0.1		0.15	%
$A_{IN_OFFSET_POS\%}$	Maximum positive input offset correction.	Differential input offsets of sine or cosine signal, percentage of transmitter coil amplitude.	+0.17		+0.23	%
$A_{IN_OFFSET_NEG\%}$	Maximum negative input offset correction.		-0.25		-0.17	%
$A_{IN_OFFSET_mV}$	Input offset correction range at typical oscillator amplitude (see Table 8).		-7.5		7.5	mV

Symbol	Parameter	Conditions	Minimum	Typical	Maximum	Units
OFF _{CORR_RES}	Input offset correction step size			0.0015		%
R _{Rx}	Coil receiver DC input resistance	Common mode to GND		20		kΩ
		Differential		100		kΩ

V_{CDM}	ESD tolerance for all pins: Charged-Device Model (CDM)	According to AEC-Q100-011 classification C3B	± 500			V
$V_{CDM,C}$	ESD tolerance for corner pins ADR_IRQN, SDA, VDDA, GND (CDM)	According to AEC-Q100-011 classification C3B	± 750			V

8. Circuit Description

The IPS2550 sensor circuit consists of one transmitter coil and two receiver coils, which are typically designed as traces on a printed circuit board. The two receiver coils have a sinusoidal shape and are shifted by 90° with respect to each other; refer to Figure 7 and Figure 8 for typical coil shapes. A metal target is placed above the coil arrangement.

Circuit signal flow:

1. The IPS2550 drives AC current into the transmitter coil and generates an alternating magnetic field.
2. The magnetic field induces voltages in the receiver coils. Without a metallic target, due to the balanced, anti-serial connection of their segments, the voltages are compensated to achieve zero output at each pair of terminals.
3. If a metal target is placed above the coils:
 - a. The magnetic field induces eddy currents on the surface of the metal target.
 - b. The eddy currents generate a counter magnetic field, thus reducing the total flux density underneath.
 - c. The voltage induced in the receiver coil areas underneath the target is reduced, creating an imbalance in the anti-serial coil segment voltages
 - d. An output voltage occurs on the terminals, changing amplitude and polarity with the target position.
4. The IPS2550 IC performs a synchronous demodulation of the received signals, and then filters and outputs them for external signal processing.

Due to the 90° phase shift of the two receiver coils, the output signals also have a 90° phase shift in relation to the target position, generating ratiometric sine and cosine signals. The signals can be converted into an absolute position, for example by applying an arctangent operation of Vsin and Vcos.

$$Position = \arctan\left(\frac{V_{sin}}{V_{cos}}\right)$$

Equation 5

8.1 Overview

Figure 6. Response of the IPS2550

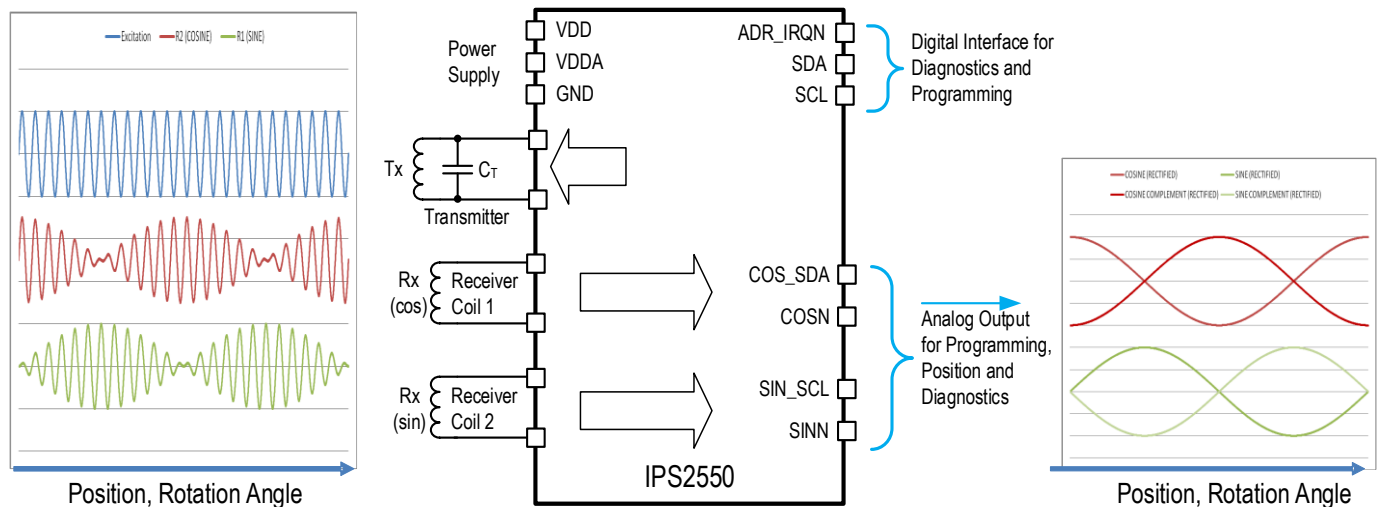

Figure 7 shows an example of a linear motion sensor with one transmitter coil (transmitter loop) and two receiver coils (Sin loop and Cos loop). Due to the alternating clockwise and counterclockwise winding direction of each segment in a loop (for example RxCos = clockwise Cos Loop1 + counterclockwise Cos Loop 2), the induced voltages in each segment have alternating opposite polarity.

$$V_{Cos\ Loop1} = -V_{Cos\ Loop2} \quad \text{Equation 6}$$

If no target is present, the secondary voltages cancel each other:

$$V_{Cos} = V_{Cos\ Loop1} + V_{Cos\ Loop2} = 0V \quad \text{Equation 7}$$

With a target placed above the coils, the secondary voltage induced in the covered area is lower than the secondary voltage without a target above it.

$$V_{Cos\ Loop1} \neq -V_{Cos\ Loop2} \quad \text{Equation 8}$$

This creates an imbalance of the secondary voltage segments, and thus, a secondary voltage $\neq 0V$ is generated, depending on the location of the target.

$$V_{Cos} = V_{Cos\ Loop1} + V_{Cos\ Loop2} \neq 0V \quad \text{Equation 9}$$

Figure 7. Coil Design for a Linear Motion Sensor

The same principles shown for the linear motion sensor in Figure 7 can be applied to an arc or rotary sensor as shown in Figure 8.

Figure 8. Coil Design for a 360° Rotary Sensor

9. Sampling Rate, Resolution, Output Data Rate, and Propagation Delay

Since the IPS2550 uses analog signal processing (no ADC), there is no sampling rate and the resolution is virtually infinite.

Due to the internal filtering and demodulation processes, there is a short signal propagation delay between analog input and output signals. This delay is factory trimmed to a fixed value, independent of the transmitter oscillation frequency.

The coil receiver circuit automatically locks to the transmitter coil oscillator frequency. It automatically corrects for LC oscillator frequency drifts due to temperature changes or air gap changes for the target.

Table 18. Propagation Delay

Symbol	Parameter	Conditions	Minimum	Typical	Maximum	Units
t_{PD}	Propagation delay of receiver input signals 1 and 2 at Sine and Cosine outputs.	Factory trimmed; over specified operating temperature and supply voltage range	3.2	4	4.9	μs

10. Output Modes

Figure 9. Output Signals: Sine-Cosine Analog Differential Mode

Figure 10. Output Signals: Sine-Cosine Analog Single-Ended Mode

11. Operating at High Speed

The IPS2550 uses analog signal processing, so it can handle inputs signals at very high speed. The input signal can have a frequency of up to 10kHz, which is equivalent to 600000 RPM (electrical phases per minute). Even higher frequencies and therefore higher speeds are possible, but with reduced performance and signal amplitude.

The mechanical rotor speed can be calculated with Equation 10:

$$rpm(mech) = \frac{rpm(el)}{coil\ periods} \quad \text{Equation 10}$$

Where

- $rpm(mech)$ Rotation speed of the rotor (and target) in revolutions per minute
- $rpm(el)$ Maximum electrical input frequency of the sensor in rpm (electrical)
= 600000 electrical periods per minute (rpm)
= 10000 electrical periods per second = 10 kHz
- $coil\ periods$ Number of electrical periods per turn
= number of coil periods per 360° circle
= number of metal target segments

For example, Figure 29 shows a design for a 6 pole motor (having 3 pole pairs) using a 3-periodic coil design.

The maximum mechanical rotation speed of this motor is calculated according to Equation 11.

$$\frac{600\text{krpm(el)}}{3} = 200\text{krpm(mech)} \quad \text{Equation 11}$$

Table 19. Output Modes and Maximum Speed

	SIN/COS Output Mode	Maximum Rotor Speed
Target Design (metal / no metal)	Sine, Cosine Cycles per Revolution	Mechanical Speed
1 × (180° / 180°)	1 × 360°	600krpm
2 × (90° / 90°)	2 × 180°	300krpm
3 × (60° / 60°)	3 × 120°	200krpm
4 × (45° / 45°)	4 × 90°	150krpm
6 × (30° / 30°)	6 × 60°	100krpm
8 × (22.5° / 22.5°)	8 × 45°	75krpm
10 × (18° / 18°)	10 × 36°	60krpm
...	1 cycle per target	600krpm / targets per wheel

12. Digital Diagnostics and Programming Interfaces

In order to program the IPS2550 and to enable fast diagnostics without interrupting the analog high speed signal path, an additional I2C digital serial interface is available.

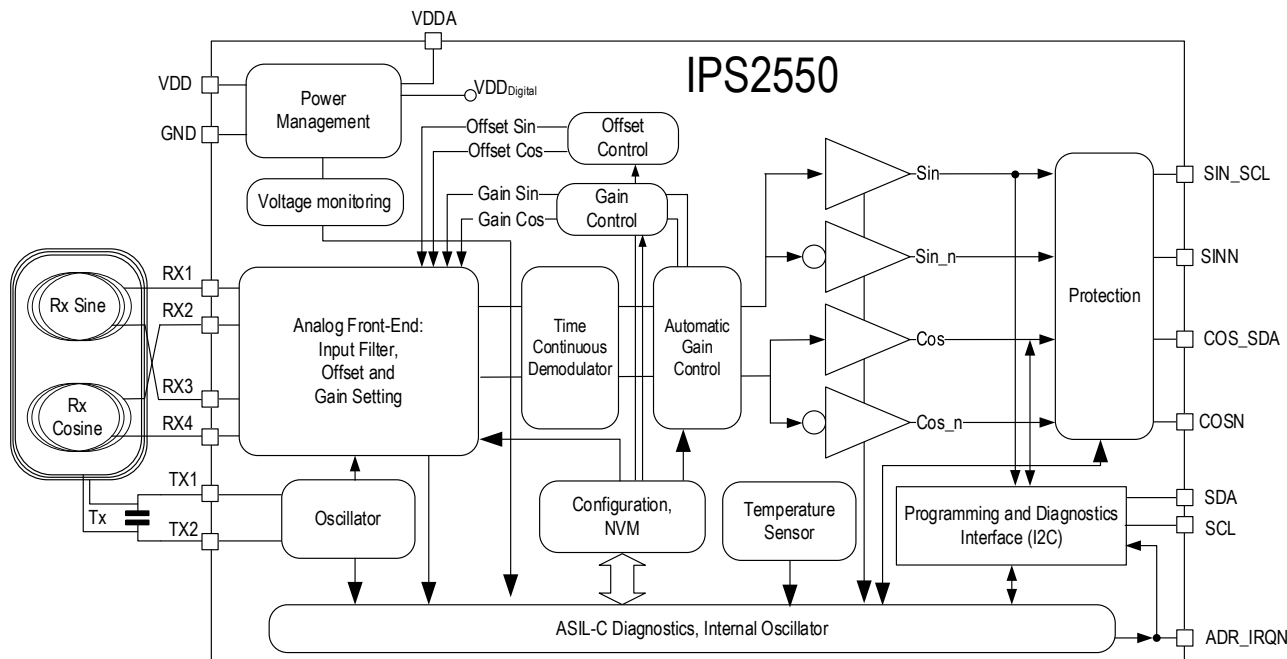

The I2C interface can be operated in two modes:

- I2C interface with address select (default)
- I2C interface with interrupt (programming option)

13. Block Diagram

Figure 11 shows the block diagram of the IPS2550.

Figure 11. Block Diagram

The main building blocks include the following:

- Power management: Power-on-reset (POR) circuit; low drop-out (LDO) regulators for analog and digital supplies.
 - Overvoltage and undervoltage monitoring for VDD, VDDA and internal voltage VDDDigital
- Oscillator: Generation of the transmitter coil signal.
- Analog front-end: Input filter, offset, and gain control for the receive signals.
 - Offset control: Correction of offsets at the receiver coil inputs RX1-RX2 and RX3-RX4.
 - Gain setting: Correction of amplitude mismatch between receiver coil input signals Rx1-RX2 and RX3-RX4.
- Time Continuous Demodulator: Converting RF amplitude modulated position signal to LF demodulated position signal.
- Gain control: Correction of amplitude mismatch from RX1/RX2 and RX3/RX4 input signals.
- Automatic Gain Control: Overall automatic adjustment of sine and cosine channel gain.
- Configuration, NVM: Nonvolatile storage of factory and user-programmable settings.
- Programming and Diagnostics Interface: Available over SIN and COS analog output interface and as a separate I2C interface.
- Temperature Sensor: Monitoring the chip temperature.
- ASIL-C Diagnosis, Internal Oscillator: Internal diagnosis of critical blocks to ensure functional safety. The factory trimmed Internal Oscillator is used for chip-internal timings and as a time base for the Transmitter frequency measurement
- 4 buffered analog/digital outputs with over-voltage and reverse-polarity protection.
- There are three interface options for the SIN_SCL, SINN, COS_SDA, and COSN pins (see Table 2):
 - Differential analog output.
 - Single-ended analog output with reference.
 - Programming

14. Detailed Block Descriptions

Refer to the block diagram in Figure 11 for an illustration of the following blocks.

14.1 Power Management

The IPS2550 can be operated with a power supply at either $VDD = 3.3V \pm 10\%$ or $VDD = 5.0V \pm 10\%$. An internal LDO generates the supply voltages for the analog and digital circuits. The analog supply (VDDA) is buffered by an external capacitor C_{VA} . The digital power supply is connected internally only.

VDD is over-voltage and reverse-polarity protected and constantly monitored for over-voltage or under-voltage.

14.2 LC Oscillator

The LC oscillator generates the RF magnetic field for the sensor. It operates in the frequency range of ~2MHz to 5MHz. The frequency is adjusted by external components L (the transmitter coil) and C (external capacitor). See Table 8 for further details.

The IPS2550 accepts a large range of coil inductance, and the coil drive current is user programmable.

The LC oscillator is continuously checked for the correct frequency or failures such as open/short circuits or an oscillator failure.

14.3 Analog Signal Path

For maximum speed, the IPS2550 uses two parallel analog signal channels: one for sine and one for cosine and all-analog signal processing.

14.3.1 Rx Coil Diagnostics

The receiver coils Rx Sine and Rx Cosine are continuously checked for open/short circuits to ground, shorts to VDD, and shorts to the opposite coil. As shown in Figure 2 and Figure 3, the receiver coils can be connected in the following two ways:

- ASIL C connection: preventing possible short-circuit of receiver coils due to a short of two neighboring pins.
- Compatibility connection: providing pin-to-pin compatibility to the industrial grade IPS2200.

14.3.2 Receiver Signal Low-Pass Filter

The receive signal is an amplitude-modulated signal where the carrier frequency is the frequency of the LC oscillator and the signal amplitude is representative of the target position. In a rotating system, the LF signals are sine and cosine shaped, where one period of the LF signal is equivalent to one period of the coil shape. See section 20 for examples of coil designs and their corresponding LF signal.

In a first step, the amplitude-modulated signals are low-pass filtered to suppress possible RF electromagnetic disturbances.

14.3.3 Offset and Gain Matching

After the signals are filtered, the RF signal is corrected for a possible offset and amplitude mismatch, originating from imperfect coil designs. The amount of offset and fine gain correction can be user programmed to a fixed value in the NVM or corrected on-the-fly in embedded applications; see section 15.1 for further details.

14.3.4 Demodulation

The time-continuous demodulator removes the carrier from the input signal, generating the demodulated LF signal.

14.3.5 Automatic Gain Control (AGC)

The signal magnitude strength of the demodulated signal, $M = \sqrt{\sin^2 + \cos^2}$, is permanently checked by a peak detector and compared against a nominal level. If needed (for example, due to change of airgap between sensor and target), the overall gain of the sine and cosine channels is corrected accordingly to bring the signal back to the nominal level.

The AGC generates an alarm if the gain leaves a user programmed range to alert for input signals that are too strong or too weak; for example from a missing target.

14.4 Signal Channel Swapping

An effective method to improve the detection of internal gain errors is a Renesas patent-pending signal channel swapping feature, available as a configuration option. When enabled, the chip periodically swaps the sine and cosine signal channels between the two analog signal paths. By applying this method, any gain mismatch between sine and cosine signal channels is immediately detectable at the analog signal outputs, even in static (non-rotating) operation.

14.5 Output Buffers

The four analog signals (sine, inverted sine, cosine and inverted cosine) are individually buffered at the corresponding output pins.

The buffer outputs are over-voltage and reverse-polarity protected and checked for shorts to ground, shorts to VDD, or common-mode voltage disruption. In the diagnostic state, if enabled, the buffers are turned off, allowing diagnostics indication by the external MCU through external pull-up or pull-down resistors.

14.6 Temperature Sensor

The IPS2550 features an internal chip temperature sensor to generate an alarm in the event of an over-temperature event. The temperature sensor has two levels of alarm:

1. The junction temperature exceeds the warning threshold: a diagnostics alarm is generated, the output buffers for SIN_SDA, COS_SCL, SINN, COSN are turned off to reduce the power consumption.
2. The junction temperature exceeds a critical alarm level. In addition, as a programming option, the LC oscillator can also be turned off to further reduce the power consumption.

Table 20. Internal Chip Temperature Sensor Characteristics

Symbol	Parameter	Conditions	Minimum	Typical	Maximum	Units
T _{OVT_WARN}	Over-temperature warning threshold		175	180	185	°C
T _{OVT_ERR}	Over-temperature error threshold		180	185	190	°C
ACC _{TS}	Temperature sensor absolute accuracy		-10		+10	°C
T _{HYST}	Temperature hysteresis		8	10	12	°C

15. ECU Connection Options

Note: In Figure 12, Figure 13, and Figure 14, the various connection options between the IPS2550 and the electric control unit (ECU) are shown. The IPS2550 must be programmed properly to match to the correct VDD voltage supply level (3.3V or 5.0V).

15.1 Embedded vs. Remote Connection

In an embedded connection, both the sensor and microcontroller (MCU) are mounted on the same printed circuit board (PCB). In these applications, the number of connections between the two chips is not critical. The MCU can take advantage of the separate digital I2C interface to constantly monitor the diagnostic registers without interrupting the analog signal flow or to change offset or gains on-the-fly.

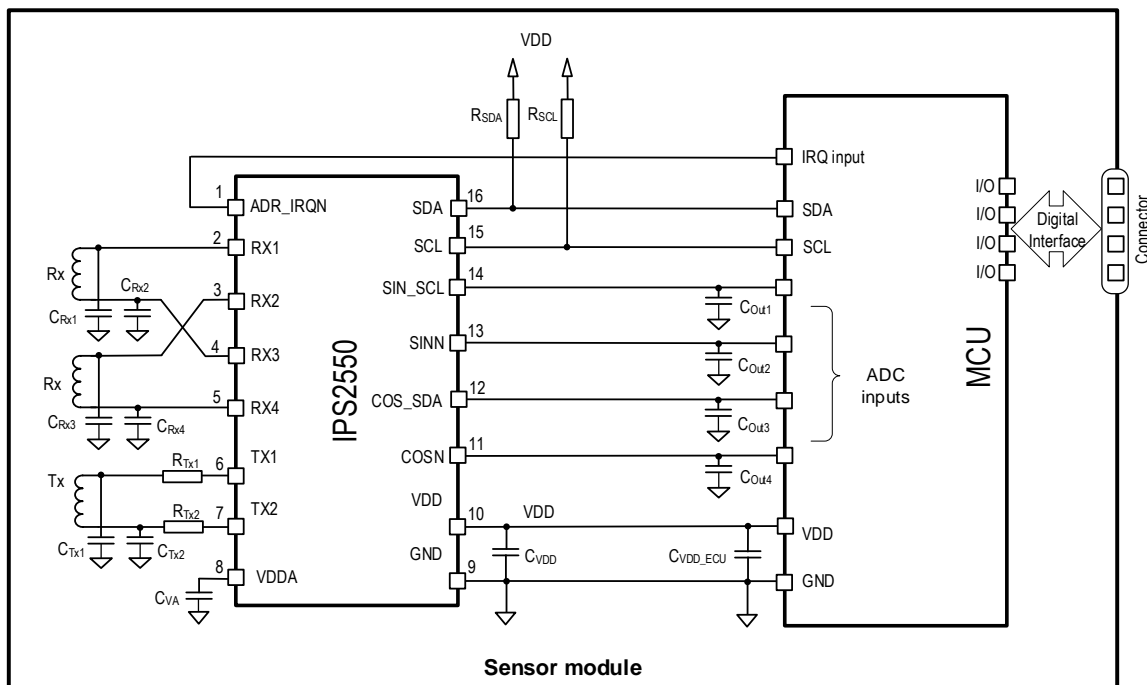

ADR_IRQ Pin is used in IRQ mode for diagnosis.

When using the digital interface pins, SDA and SCL, IPS2550 and MCU must share the same VDD voltage supply level in order to match the digital high and low signal levels.

The circuit diagram, shown in Figure 12, include external components required for improved EMC performance in embedded operation.

Note: Capacitors C_{Out1} to C_{Out4} depend on ADC input specifications of the connected MCU.

Figure 12. Embedded Application: Sensor and MCU are on the same PCB

In a remote application, the sensor module is separate from the ECU, connected by a cable. For cost efficiency, the number of wires on the cable and the number of connector pins should be kept as small as possible, typically four wires (VDD, GND, Sine, Cosine) for single-ended configuration and six wires (VDD, GND, Sine, Inverted Sine, Cosine, Inverted Cosine) for differential configuration.

In an error case, the analog outputs are switched to tristate mode; a diagnostic state is indicated by either pushing the output voltage to VDD using pull-up resistors (as shown in Figure 13) or by pulling the output voltage to ground, using pull-down resistors (as shown in Figure 14).

See 18.2 for further details on diagnostic indication.

The circuit diagrams, shown in Figure 13 and Figure 14 include external components required for improved EMC performance in remote operation.

Figure 13. Remote Application with Pull-Up Resistors for Diagnosis

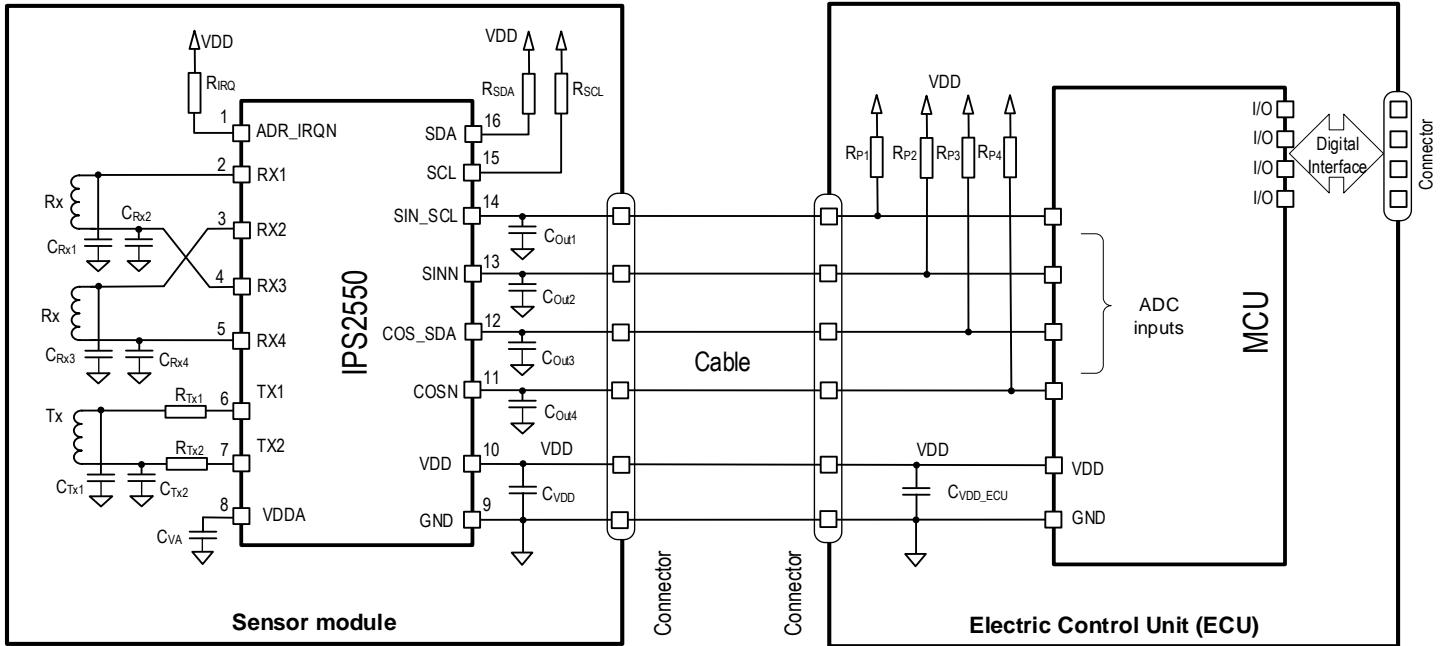

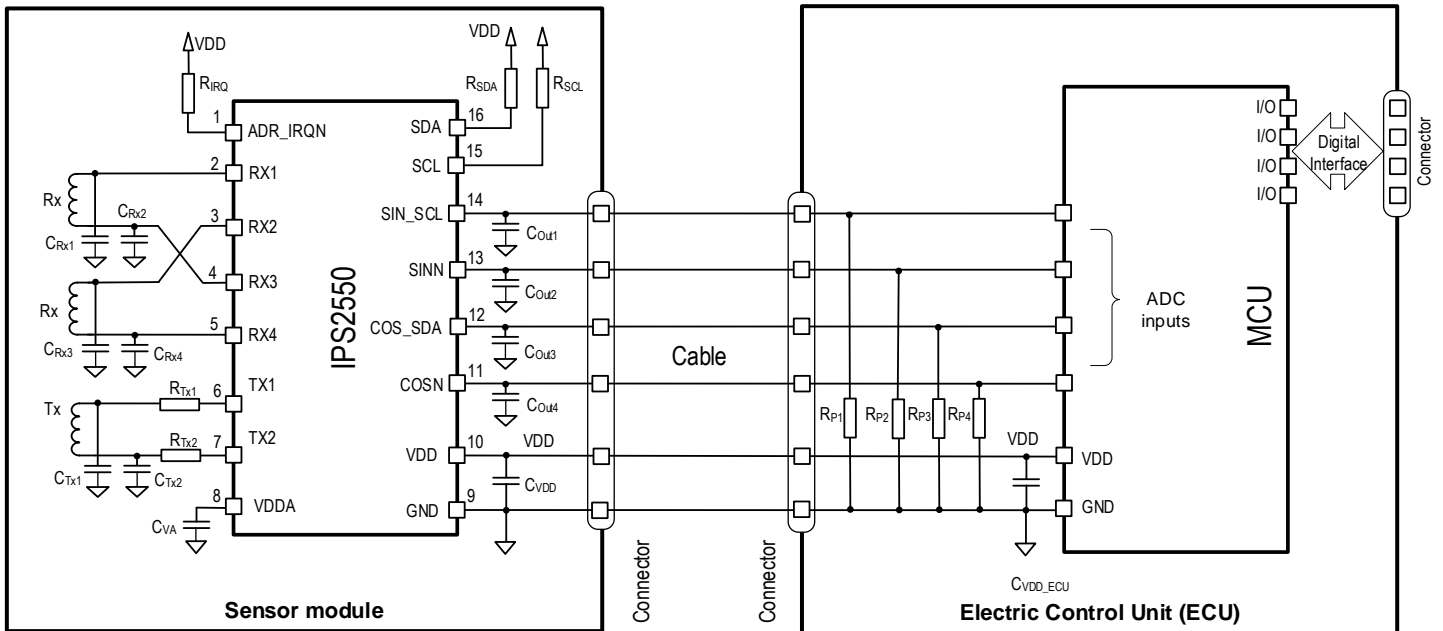

Figure 14. Remote Application with Pull-Down Resistors for Diagnosis

15.2 Supply Voltage Operation: 3.3V or 5V

The IPS2550 can be programmed to operate with either a 3.3V $\pm 10\%$ or a 5.0V $\pm 10\%$ supply voltage, the default is 5V. Refer to section 17.1 for changing the default supply voltage.”

15.3 I2C Interface

The IPS2550 includes a standard I2C interface. The I2C address is programmable. In addition, the ADR_IRQN pin can be programmed as either an I2C address selection pin or as an interrupt output (IRQN) pin when using the I2C interface (see Table 3). The IPS2550 is configured as an I2C slave; several slaves can be connected in parallel on the I2C bus. A detailed description of the programming features is available in the *IPS2550 User Programming Manual*.

Two wires, serial data (SDA, pin 16) and serial clock (SCL, pin 15), carry information between the devices connected to the bus. Both SDA and SCL are connected to the positive supply voltage VDD via an external pull-up resistor. When the bus is free, both lines are high. The output stages of devices connected to the bus must have an open-drain or open-collector to perform the wired-AND function.

An external master (host controller) initiates a transfer, generates clock signals, and terminates a transfer. The implementation supports the I2C slave function, which is addressed by the master and supports the I2C bus specification version 2.1.

Since the analog outputs might contain passive filters or EMC capacitors, the rise and fall times might be longer compared to the digital I2C interface. Therefore, the I2C clock rate during programming of the IPS2550 over the analog outputs must be adapted accordingly.

15.3.1 I2C with Address Selection (Default)

When the IPS2550 is programmed to use the I2C interface with address selection, the ADR_IRQN pin is used to select the I2C slave address by hardware pin strapping.

By default, the ADR_IRQN pin (#1) is used to define the IPS2550 I2C slave address by hardware pin strapping.

The status of this pin is mirrored in I2C address Bit A3 and the inverted status of this pin is mirrored in I2C address Bit A0 of the 7-bit I2C address (see Figure 15).

The default setting of I2C address bit is A4 =1.

If ADR_IRQN is tied to Ground, the IPS2550 default slave address is 0010001 (binary) = 0x11 (Hex), while if this pin is connected to VDD, the I2C address is set to 0011000 (binary) = 0x18 (Hex).

I2C address selection through hardware pin strapping can be disabled and a fixed I2C address can be defined in the NVM address bits A6...A3 (see further details in the *IPS2550 Programming Guide* document).

Table 21 shows the different options for selecting the I2C address by combinations of pin addressing and NVM address register setting.

I2C address bits A3 to A6 can be configured in the NVM for an individual I2C address, allowing up to 14 devices to be addressed in parallel. See the *IPS2550 Programming Guide* document for more information.

Table 21. I2C Address Selection Options in NVM

I2C Address Selection Mode	A6	A5	A4	A3	A2	A1	A0
Default setting	0	0	1	Pin#1	0	0	Pin#1 inverted
User programmable range, with I2C address selection by pin #1	001 to 110 (binary)			Pin#1	0	0	Pin#1 inverted
User programmable range, with fixed I2C address	0001 to 1110 (binary)				0	0	0

Figure 15. I2C Address Select Bits

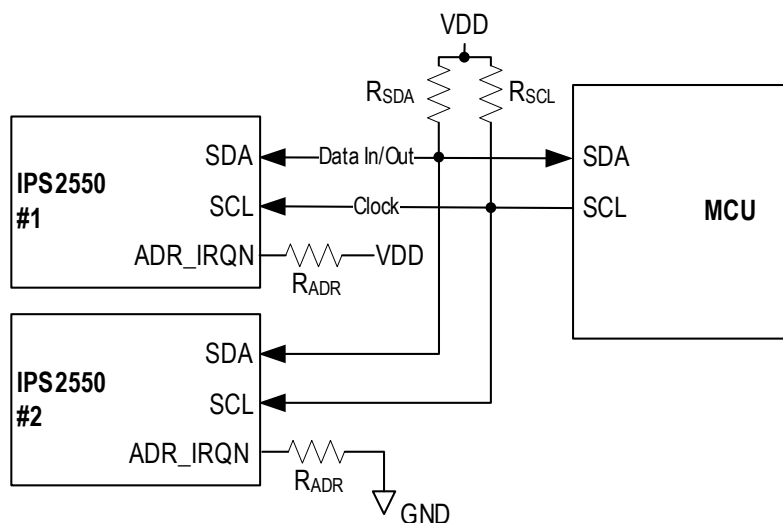

Figure 16. I2C Interface with Address Select

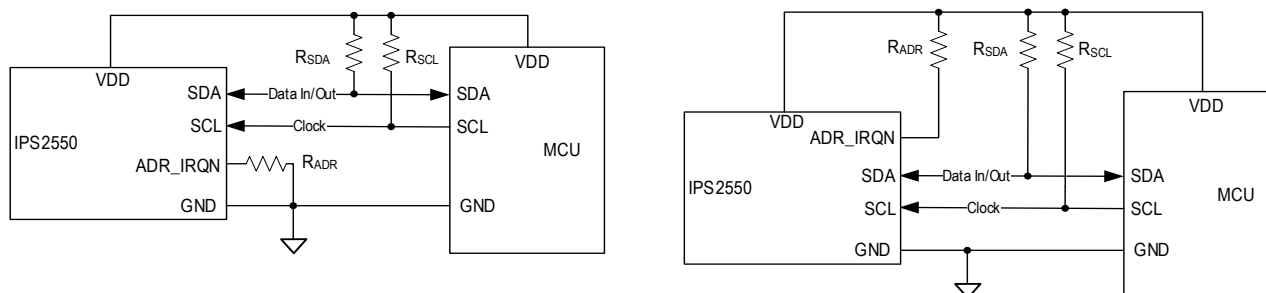

15.3.2 Avoiding a Parasitic Path through ADR_IRQN Pin during Loss of GND or Loss of VDD

In safety critical applications, a loss of ground or VDD must be monitored and reacted to in case of failure. Cases for a loss of the GND or VDD wire in a remote application and their proper diagnostic configuration are shown in Figure 24.

If the ADR_IRQN pin is used for selecting the I2C address through hardware pin strapping, it is recommended not to connect it directly to VDD or GND. Connected it to VDD or GND with a 4.7kΩ resistor (see Figure 17) to avoid parasitic supply currents flowing through the ADR_IRQN pin in case of broken GND or VDD wires that might put the chip in an undefined state.

Figure 17. I2C Interface with Address Selection by Hardware Pin Strapping Through ADR_IRQN Pin

15.3.3 I2C Interface with Interrupt (Programming Option)

When the IPS2550 is programmed to use the I2C interface with the interrupt function, it operates as a standard I2C interface. The I2C address is programmable. In addition, the ADR_IRQN pin is used as an interrupt output for fast signaling of a diagnostic event.

Figure 18. I2C Interface Configuration with Interrupt on a Single Slave

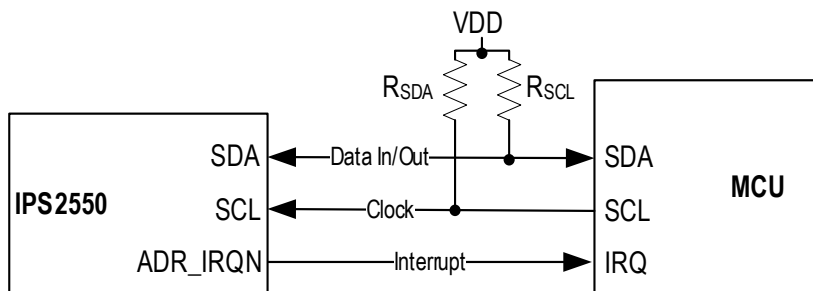

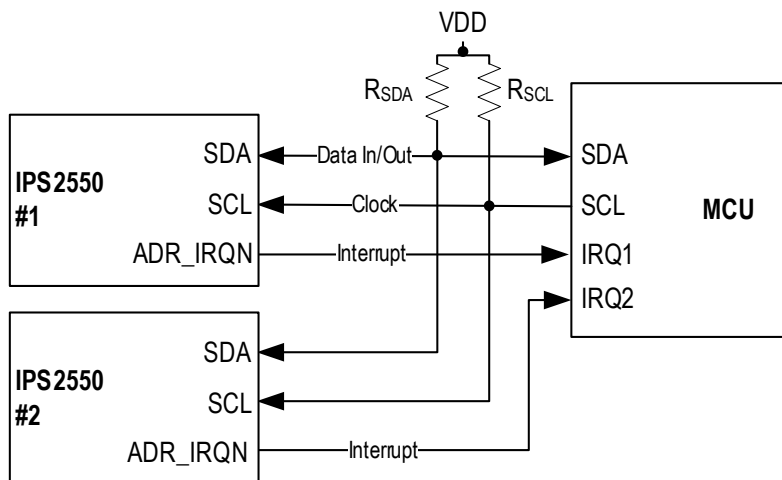

Figure 19. I2C Interface Configuration with Multi-slave Interrupt

Note: In this mode, several I2C slaves are connected in parallel. Note that each I2C slave must have an individual I2C address.

For a detailed description of the I2C interface, refer to the *IPS2550 Programming Guide*.

16. Over-Voltage Protection

16.1 I/O Protection

In order to meet the automotive requirements for over-voltage and reverse-polarity protection on both the output and power supply pins, the IPS2550 includes several protection and diagnosis features:

1. Protection against short circuit of the output pins SIN, SINN, COS, and COSN to GND or to VDD
2. Over-voltage and reverse-polarity protection:
 - a. On supply pin VDD to GND
 - b. On analog output pins SIN, SINN, COS, and COSN to GND

17. Programming Options

The IPS2550 family offers a variety of programming options. The main programming functions are described in Table 22.

The IPS2550 can be accessed and programmed in one of two ways:

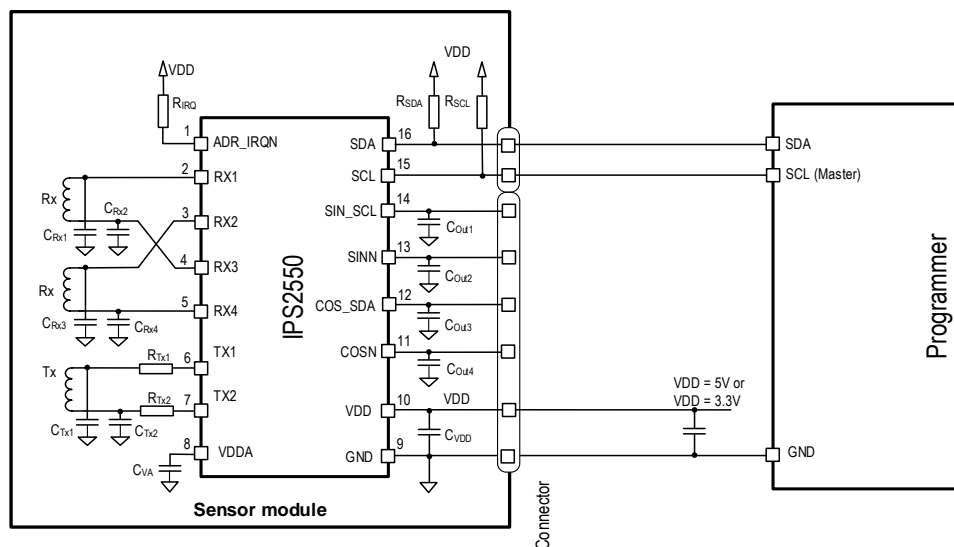

- Over the I2C interface pins SDA and SCL
- Through the analog outputs SIN_SCL and COS_SDA

Note: For programming details, see the *IPS2550 Programming Guide*, which is available from Renesas on request.

The I2C interface, available at pins SDA and SCL, allows simultaneous access to the internal registers and on-the-fly modification of gain and offset settings without interruption of the analog output signals. The IPS2550 can also be programmed via this interface in the same way using a standard I2C protocol; see Figure 20.

Note that the SDA and SCL pins do not contain internal pull-up resistors. If this interface is used, external pull-up resistors need to be installed, either on the sensor module or externally.

Figure 20. Programming the IPS2550 over the I2C Interface

In some cases, particularly in remote applications, where the number of connector pins and wires is kept at a minimum and where permanent access to the internal registers is not needed, it is also possible to program the IPS2550 over two analog outputs (SIN_SCL and COS_SDA; see Figure 21).

This method is typically used for end-of-line programming for a final, assembled sensor module, where the digital interface pins SDA and SCL are no longer accessible.

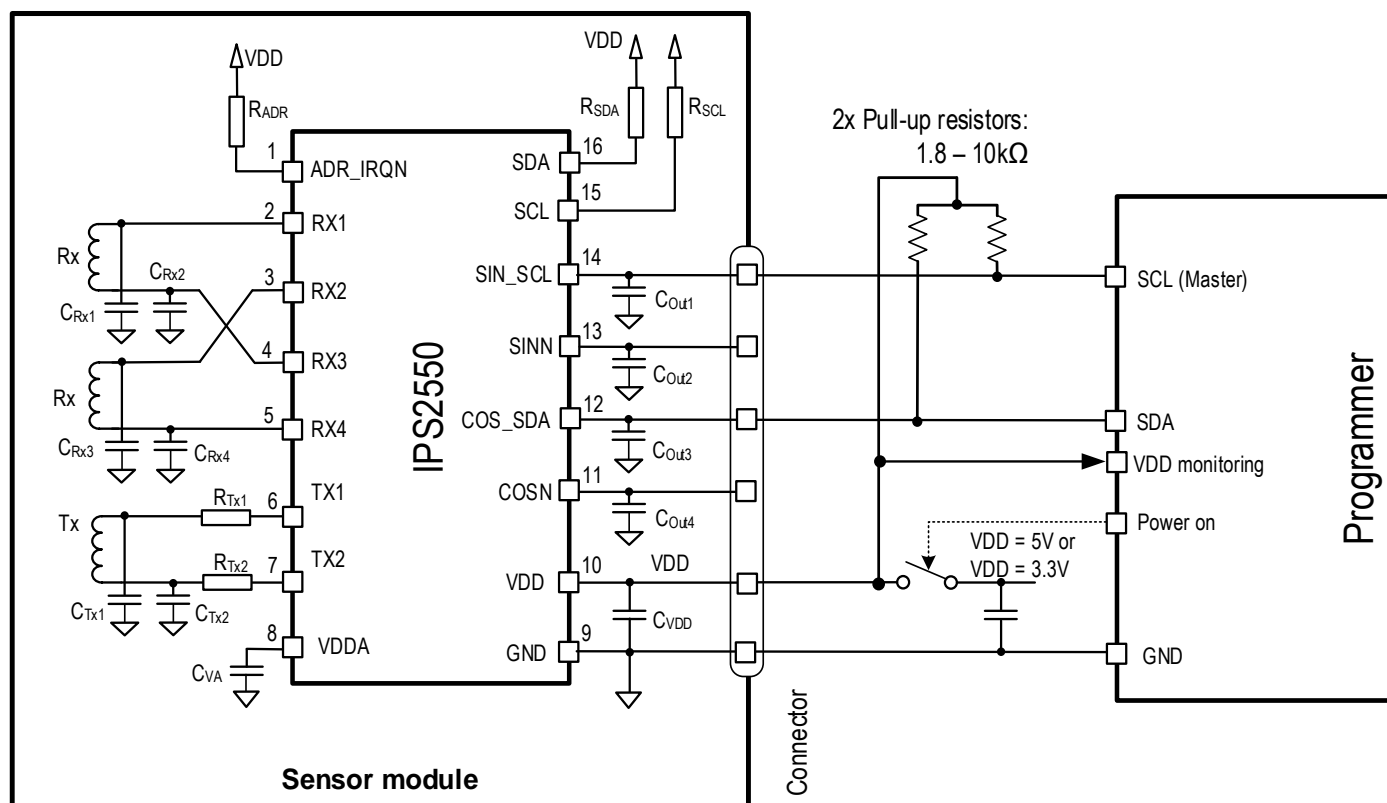

In order to avoid unintentional programming of the IPS2550, a few safety locks are implemented:

- The programming enable window is open for a few milliseconds after power-up. If there is no external enable command sent within this time window, the IPS2550 resumes normal power up.
- Following this first level of enabling programming mode, another password must be sent within a second, longer window to unlock Programming Mode. See the *IPS2550 Programming Guide* document for details.
- After programming, the chip can be locked for further writing, and in addition it can also be locked for reading. Once the chip is locked, it cannot be unlocked (Cyber Security feature).

Since the analog outputs could contain external passive EMC filters that will slow down the data rate, the programmer must also be able to run at lower speeds.

In order to hit the programming time window after power-up, the programmer must be able to sense the VDD ramp-up of the IPS2550. Optionally, the programmer can actively cycle the power for the IPS2550 as illustrated in Figure 21.

Figure 21. End of Line Programming of the IPS2550 Through the Analog Outputs

Note: For improved EMC and ESD performance, do not leave unused I2C interface pins floating. Connect the SCL and SDA pins to VDD using series resistors R_{SDA} and R_{SCL} , see Table 13 for recommended component values.

17.1 Programming the Device to Use the Other Supply Voltage Option

The IPS2550 can be programmed for two operation supply voltages: 3.3V \pm 10% or 5.0V \pm 10%.

If an IPS2550 that is programmed for 5V supply is connected to a 3.3V supply, it will remain in a (5V) under-voltage state and not boot up. However, in this state, the NVM Programming Mode can be enabled, so the chip can be re-programmed to a 3.3V supply voltage. After a power-on-reset, the IPS2550 will re-boot as a 3.3V device and operate normally in a 3.3V environment.

If an IPS2550 that is programmed for 3.3V supply is connected to a 5V supply, it will start-up, flag a (3.3V) over-voltage alarm, and enter the diagnostic state. However, despite the alarm, Programming Mode can still be enabled, so the IPS2550 can be re-programmed to 5V supply voltage. After a power-on-reset, the IPS2550 will re-boot as a 5V device and operate normally in a 5V environment.

17.2 Lock Feature (Cyber Security)

The IPS2550 contains a lock bit option, which can be set by the user. The lock feature is user selectable for write lock only or read+write lock. Once the write lock bit or write+read lock bit is set, no further writing to the IPS2550 is possible. A locked IPS2550 cannot be unlocked.

Note: The detailed IPS2550 Programming Guide is available from Renesas on request.

17.3 Programming Options

Table 22. Programming Options Overview

Function	Programming Option
Supply voltage range	3.3V \pm 10% or 5.0V \pm 10%, alarm levels
High speed interface	Sine/cosine differential or single-ended
Digital diagnostic and programming interface	I2C with address select or I2C with interrupt
I2C interface	Slave address, I2C mode with address select or with interrupt
Diagnostic signaling on high speed analog interface	Analog output pins are high ohmic in diagnostic state. (SIN, COS) and (SINN, COSN) can be enabled/disabled separately
Security lock function	Access to internal registers of the device can be set to read-only or R/W lock
Receiver overall gain	Overall gain coarse adjustment
Sine, cosine channel gain	Amplitude mismatch correction, fine adjustment
Sine, cosine offset	Pre-adjustment of input offsets
Transmitter oscillator	Bias current, optimization of coil performance
Time base counter	Measurement of transmitter oscillator frequency, and upper/lower frequency alarm
Interrupt	Enable/disable/clear interrupt events
Automatic gain control	Upper/lower gain limit

18. Functional Safety and Diagnostics

18.1 Functional Safety ASIL and ISO Compliance

The IPS2550 has been developed according to ISO26262 as a Safety Element out of Context (SEooC) for implementation in safety relevant systems up to ASIL C for a single IC and ASIL D for dual, redundant ICs, using internal and external safety mechanisms.

Integration of IPS2550 products into safety-related applications requires a safety analysis performed by the user.

Internal safety mechanisms include, but are not limited to, the following:

- Detection of broken or shorted receive or transmitter coils
- Under-voltage and over-voltage detection
- Broken-chip detection
- Data integrity checks (ECC and parity)
- Silicon chip over-temperature detection
- Detection of output buffer failures

See Table 26 for additional IPS2550 safety features.

External safety mechanisms must be performed by the receiving microcontroller unit (MCU). They include, but are not limited to, the following:

- Cable harness checks (open, short to GND, short to VDD)
- Plausibility and failure checks of the sine and cosine signals (offset, amplitude, phase)
- Position output synchronicity (for systems using dual ICs)

18.2 Diagnostic Mode Indication through Analog Outputs

In addition to the diagnostic flag indication through the I2C interface and interrupt output pins, the IPS2550 offers diagnostic indication through the analog output pins by putting them in diagnostic mode. This diagnostic mode is indicated by an output voltage that is outside the normal operating range, see Figure 22.

Figure 22. Operating Range and Diagnostic Range

When the AGC is enabled, the normal operating range is:

- $VDD/2 \pm 1.5V = 1.0$ to $4.0V$ for 5V mode
- $VDD/2 \pm 900mV = 0.75$ to $2.55V$ for 3.3V mode or 5V mode (default)

When the AGC is disabled, the operating output voltage range is not limited and defined by the input voltage multiplied by the total gain in the signal path. Note that the gain has to be set correctly otherwise the output voltage moves into the diagnostic ranges.

The limits for the diagnostic ranges are defined by the user. Typical diagnostic ranges are:

- Diagnostic low ≤ 3 to 5% VDD
- Diagnostic high ≥ 95 to 97%VDD.

For the IPS2550, the output voltage in diagnostic mode depends on the error condition and the value of the external pull-up or pull-down resistors, see Table 24 and Table 25 for details.

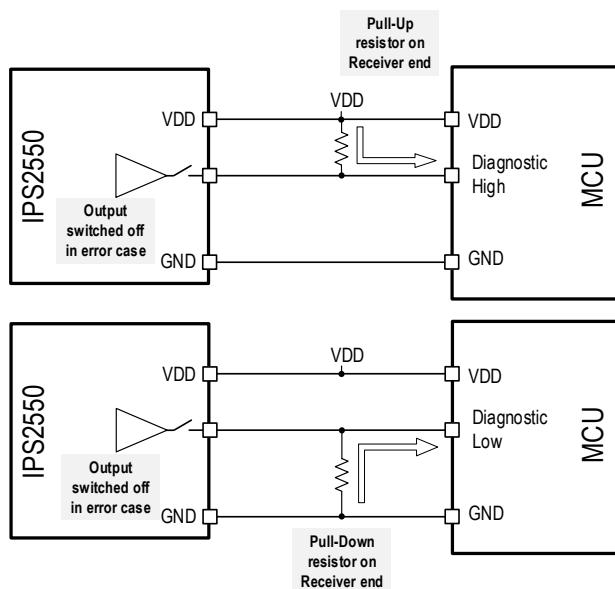

The IPS2550 provides the following options for diagnostics indication through the analog outputs:

- Diagnostics indication on output pins disabled
- Diagnostics only on SIN_SCL and COS_SDA pins
- Diagnostics only on SINN and COSN pins
- Diagnostics on all four analog output pins

Each individually checked error can be enabled or disabled for diagnostics indication.

If diagnostic is enabled and an error occurs, the selected outputs are switched off. By connecting external pull-up or pull-down resistors, the output voltage is either pulled towards VDD into the Diagnostic high range or pulled towards GND into the Diagnostic low range, see Figure 23.

Figure 23. Selection of Diagnostic Range

Note that during programming through the analog outputs using the I2C interface, the SIN_SCL and COS_SDA pins need to be connected to external pull-up resistors. If the Sensor module includes on-board pull-down resistors, the external pull-up resistors for programming must be selected properly to provide adequate high levels that does not exceed the load current on the outputs. Therefore, if the IPS2550 is to be programmed on module level, for example for end-of-line calibration, the use of pull-up resistors for diagnostics indication is recommended.

18.2.1 Shorted and Broken Wire Detection

A failure from a broken or shorted wire occurs when the sensor is connected to a control unit (MCU, ECU) by a cable.

18.2.1.1 Shorted Wires

Shorts between Ground, Signal and Supply wires can be safely detected, as shown in Table 23:

Table 23. Detection of Shorts between Wires

Cable connections	Supply	Output	Ground
Supply	Short between two supplies. Only applicable for isolated, redundant sensor IC supplies. Must be monitored and controlled by the external power supply unit supplying the sensors.	Short between Supply and Output. Output switches off when the output current exceeds the overcurrent threshold. Diagnostic state depends on whether pull-up or pull-down resistors are installed at the receiver side.	Short between Supply and Ground. Overcurrent in the supply line. Must be monitored and controlled by the external power supply unit supplying the sensor.
Output	Short between Output and Supply. Output switches off when the output current exceeds the overcurrent threshold. Diagnostic state depends on whether pull-up or pull-down resistors are installed at the receiver side.	Short between two different outputs. Outputs switch off when their output current exceeds the overcurrent threshold. Diagnostic state depends on whether pull-up or pull-down resistors are installed at the receiver side.	Short between Output and Ground. Output switches off when the output current exceeds the overcurrent threshold. Diagnostic state depends on whether pull-up or pull-down resistors are installed at the receiver side.
Ground	Short between Ground and Supply. Overcurrent in the supply line. Must be monitored and controlled by the external power supply unit supplying the sensor.	Short between Ground and Output. Output switches off when the output current exceeds the overcurrent threshold. Diagnostic state depends on whether pull-up or pull-down resistors are installed at the receiver side.	Short between two Ground wires. Only applicable for isolated, redundant sensor IC supplies. Must be monitored and controlled by the external power supply unit supplying the sensors"

18.2.1.2 Broken Wires

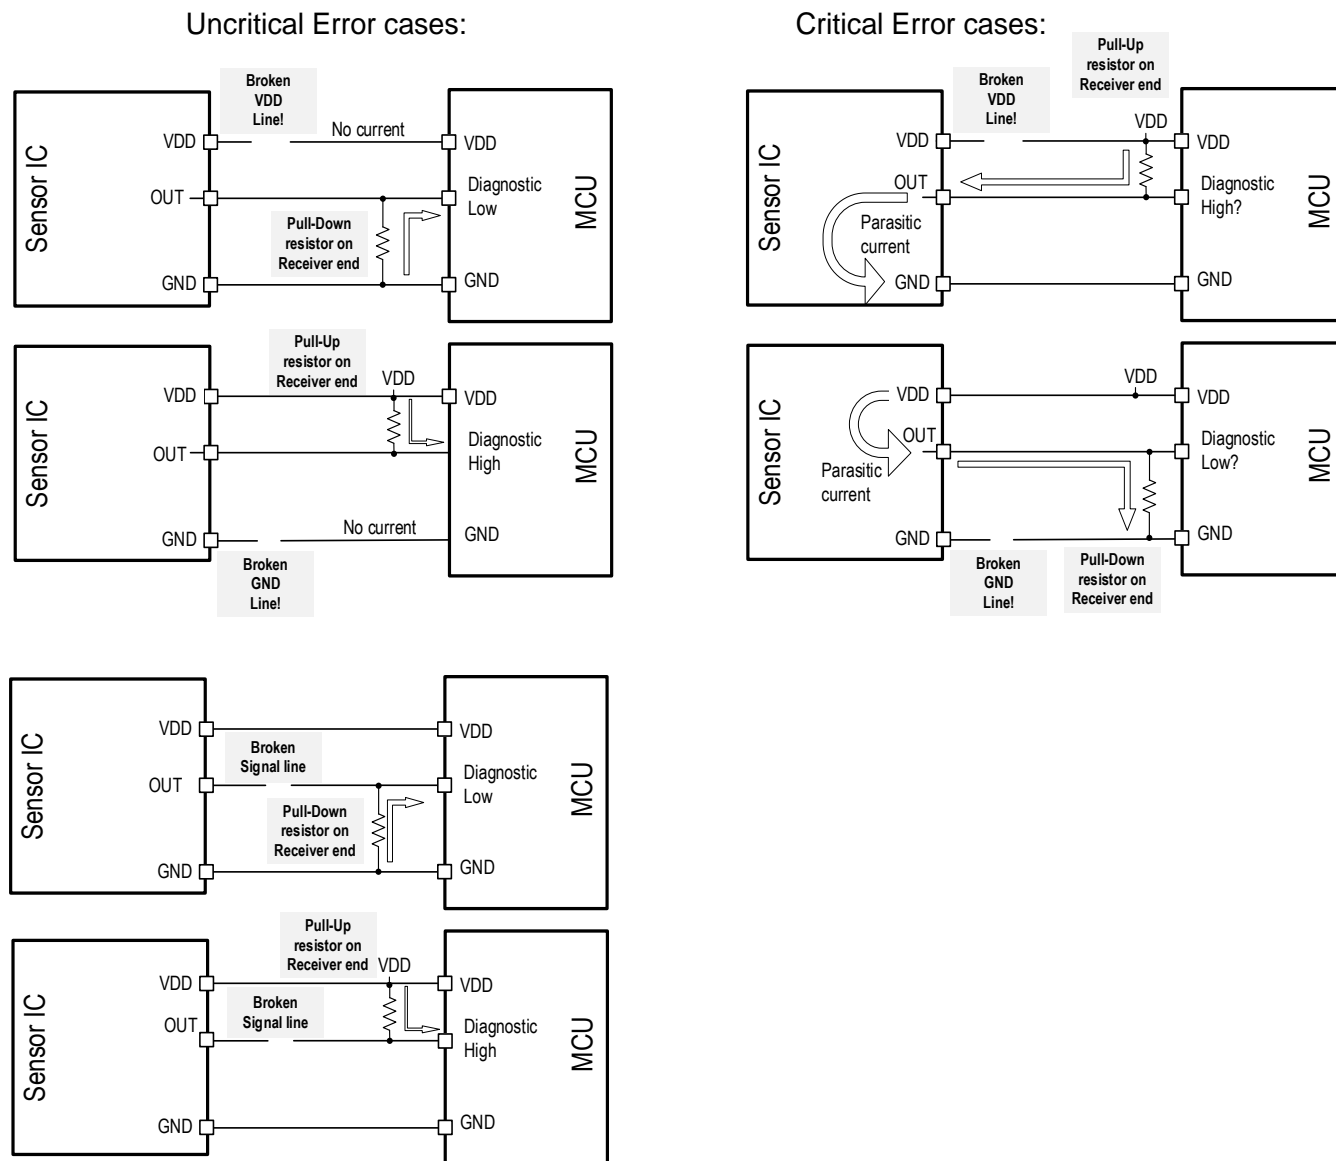

Most of the broken Supply, GND, or Signal wire errors are easily detectable, see the left column of Figure 24.

For the following cases, the parasitic current inside the Sensor IC can cause unwanted, too high voltage drops across the pull-up or pull-down resistors and does not indicate the error condition properly (see right column of Figure 24):

- a broken Supply wire with external pull-up resistors at the receiving end:
parasitic current flows from VDD on the receiver end → external pull-up resistor → output pin of the Sensor IC → device internal parasitic path to GND.
- a broken GND wire with external pull-down resistors at the receiving end:
parasitic current flows from VDD on the Sensor IC → device internal parasitic path to output pin → external pull-down resistor → GND

For these special cases, the maximum resistance value for these resistors must be selected according to the required diagnostic range, see Table 24 and Table 25.

Figure 24. Parasitic currents with Broken VDD or Broken GND lines

In case of an open connection of the VDD or GND pins, a parasitic supply current can flow through other pins (such as ADR_IRQN, SDA or SCL) if they are directly connected to VDD or GND, see Figure 25. To avoid such parasitic supply currents, connect these pins to VDD or GND via a $\geq 4.7\text{k}\Omega$ resistor, as shown in Figure 25.

Figure 25. Parasitic currents through ADR_IRQN pin

Critical Error cases, using ADR_IRQN as Input:

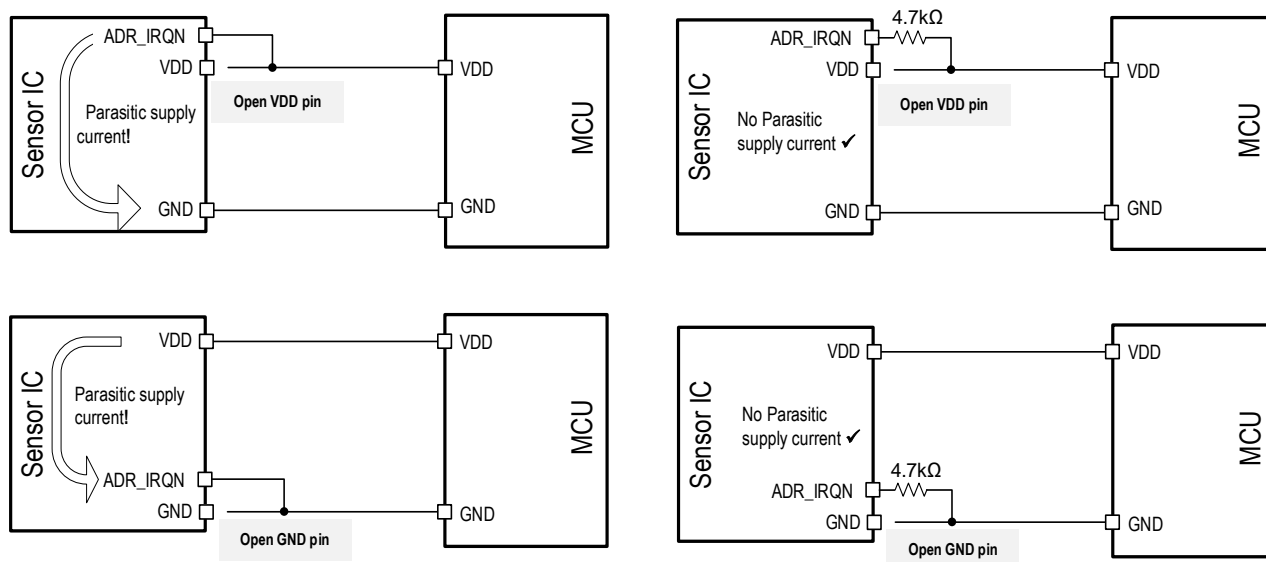

Table 24. Diagnostic Levels with Pull-Up Resistors

Diagnostic Level	>95% VDD	>96% VDD	>97%VDD	Unit
Error indication during normal operation	≤ 10			k Ω
Broken GND line	Not critical, see Figure 24, left column			k Ω
Broken VDD line, 5V mode	≤ 4.7	≤ 3.82	≤ 2.84	k Ω
Broken VDD line, 3.3V mode	≤ 3.96	≤ 3.2	≤ 2.4	k Ω

Table 25. Diagnostic Levels with Pull-Down Resistors

Diagnostic level	<3% VDD	<4% VDD	<5%VDD	Unit
Error indication during normal operation	≤ 10			k Ω
Broken VDD line	Not critical, see Figure 24, left column			k Ω
Broken GND line, 5V mode	≤ 1.48	≤ 2.0	≤ 2.56	k Ω
Broken GND line, 3.3V mode	≤ 1.65	≤ 2.23	≤ 2.85	k Ω

Note: Another potential parasitic supply current path during open GND pin or open VDD pin connection can occur when the ADR_IRQN pin is used as I2C address selector and hard-wired to GND or VDD. See chapter 15.3.2 for details. It is therefore recommended to connect the ADR_IRQN pin to GND or VDD using a series resistor R_{ADR} . See Table 13 for recommended component values.

18.3 Diagnostic Features

The diagnostics described in Table 26 are performed on the chip level and are flagged in corresponding registers if a fault detection occurs. Each of these diagnostic functions can be enabled or disabled to generate an interrupt event at the ADR_IRQN output. In addition, an interrupt event can also be signaled through the high speed interface pins (SIN, SINN, COS, COSN; see Table 2) by putting them into the diagnostic state.

Alarm types marked as “Static” will remain set while the error persists and are cleared only by power-on-reset (POR); alarm types marked as “Temporary” will be cleared when the source of the error is removed.

Diagnostic flags marked as “Continuous” are continuously tested; diagnostic flags marked as “Start-up” are checked at start-up only.

Table 26. Diagnostic Features

Diagnostic Flag	Type	Active	Description
VDD over-voltage	Temporary	Continuous	If the external supply voltage exceeds the maximum limit of typical +10%, this flag is asserted. To avoid a flag toggling, a comparator hysteresis is implemented. See Table 6 for alarm levels in 3.3V Mode and Table 7 for alarm levels in 5V Mode.
VDD under-voltage	Temporary	Continuous	If the external supply voltage falls short of the minimum limit of typical -10%, this flag is asserted. To avoid flag toggling, a comparator hysteresis is implemented. See Table 6 for alarm levels in 3.3V Mode or Table 7 for alarm levels in 5V Mode.
VDDA under-voltage	Temporary	Continuous	Under-voltage condition at VDDA. See Table 6 for alarm levels in 3.3V Mode or Table 7 for alarm levels in 5V Mode.
Data access failure	Temporary	Continuous	Chip internal failure.
Protocol integrity failure	Temporary	Continuous	Failure in the I2C data transfer.
Shadow register DED	Static	Continuous	Shadow register bank double-bit error detection (DED).
Shadow register SED	Temporary	Continuous	Shadow register bank single-bit error detection (SED). Each single-bit error detection triggers a single-bit error correction (SEC) of the register output.
Nonvolatile memory DED	Static	Start-up	NVM double-bit error detection. Each individual addressed word is checked and flagged for bit error.
Nonvolatile memory SED	Temporary	Start-up	NVM single-bit error detection. Each individual addressed word is checked and flagged for bit errors. Each single-bit error detection will automatically trigger a single-bit error correction (SEC) of the NVM output.
LC oscillator frequency failure	Temporary	Continuous	This flag is set when the LC oscillator frequency is out of range. The frequency range is programmable.
LC oscillator general failure	Temporary	Continuous	This flag is set when the LC oscillator stops running.
Internal oscillator failure	Static	Continuous	Failure of the chip internal oscillator.
Internal bus failure	Temporary	Continuous	Chip internal failure.
IRQN watchdog failure	Static	Continuous	A cyclic interrupt request can be initiated by starting a watchdog counter. Once the timer is expired, the interrupt flag is asserted and the timer will be restarted. The timer can be stopped by resetting the watchdog value to zero.
Mechanical damage	Static	Continuous	The chip is checked for mechanical damage (cracks in the silicon).

Diagnostic Flag	Type	Active	Description
Output buffer failure	Temporary	Continuous	This flag is set when the mean value of analog outputs (SIN+SINN) or (COS+COSN) differs from (VDD/2) by more than specified limits, see parameter DC_{OFF_AL} in Table 11. This error will always turn off the analog outputs, regardless of the analog output diagnostics mode.
	Static		If the output buffer failure condition still persists after eight temporary buffer failure checks, all four analog outputs are permanently turned off to avoid overheating of the chip and the static output buffer failure flag is set. This state can be cleared by power-on-reset or by clearing the static output buffer failure flag through the I2C interface.
Output buffer overload	Temporary	Continuous	This flag is set when the load current on one or more analog output buffers is above the overcurrent limit (I_{OL}). After a debounce time t_{oc_assert} , all four outputs are switched off (tri-state). A temporary output overload check is performed following debounce time $t_{oc_deassert}$: the outputs are turned on and the overcurrent condition is asserted again. See Table 11 and Table 12 for parameters.
	Static		If the output overload condition still persists after 8 temporary output overload checks, all four analog outputs are permanently turned off to avoid overheating of the chip and the static output buffer overload flag is set. This state can be cleared by power-on-reset or by clearing the static output buffer overload flag through the I2C interface.
Receiver coils failure	Temporary	Continuous	This flag is set if one of the following malfunctions of the receiver coils occurs: short between coils, short to GND, short to VDD, open coil.
Transmitter coil failure	Temporary	Continuous	This flag is set if there is failure at the transmitter coil.
Junction temperature warning/failure	Temporary	Continuous	Over-temperature warning or failure of the chip internal temperature sensor.
Internal supply failure	Static	Continuous	Failure of the chip's internal supply voltages.
AGC error	Temporary	Continuous	This flag is set when the gain of the AGC has reached user programmed limits.
Internal digital error	Static	Continuous	Error of the internal digital circuit.
BIST diagnostics error	Static	Start-up	Failure of self-test mechanisms.

18.4 Internal Register and Memory Errors

For all registers, volatile and nonvolatile memories, an error correcting code (ECC) is implemented, allowing 2-bit error detection and 1-bit error correction. An alarm flag is set when an ECC error occurs.

18.5 LC Oscillator Frequency Out of Range

The typical LC oscillator frequency ranges from ~2MHz to 5MHz, between the medium-wave radio band (0.52MHz to 1.73MHz) and the short-wave radio band (5.8MHz to 6.3MHz). Due to the use of external components (printed inductor and discrete capacitor), the transmitter oscillation frequency will change over temperature, mainly depending on the temperature coefficient of the discrete capacitor (see C_T in the application circuit on page 1).

Recommendation: Use a capacitor with a low temperature coefficient.

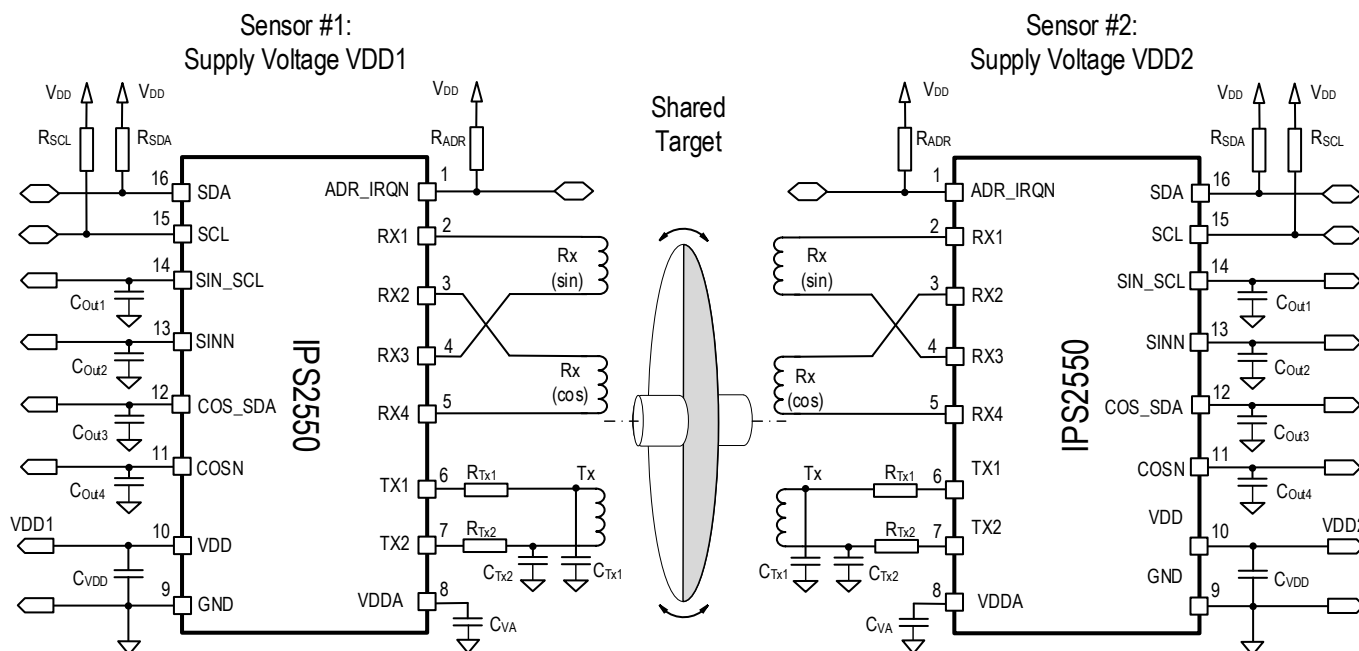

In order to ensure that the oscillation frequency is within the boundaries of a given application, the oscillation frequency of the transmitter oscillator is internally measured and stored as a proportional value in a register. The user can select upper and lower limits for these register values that will create an alarm flag when the oscillation frequency is outside of these programmable boundaries.

19. Redundant Connections

In applications requiring extended reliability, a redundant set-up using two separate IPS2550 circuits can be used, as shown in Figure 26. Physically, they share the same target and share the same coil area but are electrically isolated from one another with the transmitter and receiver coils placed at different PCB layers.

Depending on the coil design, the two transmitter coils can be magnetically coupled with each other. For fail-safe operation, the ideal coupling between the two transmitter coils needs to be evaluated in each case.

Figure 26. Application Diagram: Dual Redundant Sensors, Dual Supply

20. Application Examples

Typical coil and target arrangements are shown in Figure 27 to Figure 30: As examples, rotary designs for $1 \times 360^\circ$, $2 \times 180^\circ$, $3 \times 120^\circ$ and $4 \times 90^\circ$ are shown. Many other combinations (essentially any $n \times 360/n$) are possible, where n is an integer number.

For example, in sensor designs for brushless DC rotor position feedback, n could be the number of pole pairs on the rotor. In such cases, the output signal of the IPS2550 would be one electric period per each pole pair.

Note that multi-periodic designs improve the mechanical accuracy, compared to a one-periodic coil design. A 4-periodic coil design ($4 \times 90^\circ$) has a typical mechanical accuracy of $\pm 0.2\%$ per $90^\circ = \pm 0.18^\circ$

Figure 27. Coil Design and Signal Output for a 360° Rotary Sensor

Notice

1. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation or any other use of the circuits, software, and information in the design of your product or system. Renesas Electronics disclaims any and all liability for any losses and damages incurred by you or third parties arising from the use of these circuits, software, or information.
2. Renesas Electronics hereby expressly disclaims any warranties against and liability for infringement or any other claims involving patents, copyrights, or other intellectual property rights of third parties, by or arising from the use of Renesas Electronics products or technical information described in this document, including but not limited to, the product data, drawings, charts, programs, algorithms, and application examples.
3. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.
4. You shall be responsible for determining what licenses are required from any third parties, and obtaining such licenses for the lawful import, export, manufacture, sales, utilization, distribution or other disposal of any products incorporating Renesas Electronics products, if required.
5. You shall not alter, modify, copy, or reverse engineer any Renesas Electronics product, whether in whole or in part. Renesas Electronics disclaims any and all liability for any losses or damages incurred by you or third parties arising from such alteration, modification, copying or reverse engineering.
6. Renesas Electronics products are classified according to the following two quality grades: "Standard" and "High Quality". The intended applications for each Renesas Electronics product depends on the product's quality grade, as indicated below.

"Standard": Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; industrial robots; etc.

"High Quality": Transportation equipment (automobiles, trains, ships, etc.); traffic control (traffic lights); large-scale communication equipment; key financial terminal systems; safety control equipment; etc.

Unless expressly designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not intended or authorized for use in products or systems that may pose a direct threat to human life or bodily injury (artificial life support devices or systems; surgical implantations; etc.), or may cause serious property damage (space system; undersea repeaters; nuclear power control systems; aircraft control systems; key plant systems; military equipment; etc.). Renesas Electronics disclaims any and all liability for any damages or losses incurred by you or any third parties arising from the use of any Renesas Electronics product that is inconsistent with any Renesas Electronics data sheet, user's manual or other Renesas Electronics document.

7. No semiconductor product is absolutely secure. Notwithstanding any security measures or features that may be implemented in Renesas Electronics hardware or software products, Renesas Electronics shall have absolutely no liability arising out of any vulnerability or security breach, including but not limited to any unauthorized access to or use of a Renesas Electronics product or a system that uses a Renesas Electronics product. RENESAS ELECTRONICS DOES NOT WARRANT OR GUARANTEE THAT RENESAS ELECTRONICS PRODUCTS, OR ANY SYSTEMS CREATED USING RENESAS ELECTRONICS PRODUCTS WILL BE INVULNERABLE OR FREE FROM CORRUPTION, ATTACK, VIRUSES, INTERFERENCE, HACKING, DATA LOSS OR THEFT, OR OTHER SECURITY INTRUSION ("Vulnerability Issues"). RENESAS ELECTRONICS DISCLAIMS ANY AND ALL RESPONSIBILITY OR LIABILITY ARISING FROM OR RELATED TO ANY VULNERABILITY ISSUES. FURTHERMORE, TO THE EXTENT PERMITTED BY APPLICABLE LAW, RENESAS ELECTRONICS DISCLAIMS ANY AND ALL WARRANTIES, EXPRESS OR IMPLIED, WITH RESPECT TO THIS DOCUMENT AND ANY RELATED OR ACCOMPANYING SOFTWARE OR HARDWARE, INCLUDING BUT NOT LIMITED TO THE IMPLIED WARRANTIES OF MERCHANTABILITY, OR FITNESS FOR A PARTICULAR PURPOSE.
8. When using Renesas Electronics products, refer to the latest product information (data sheets, user's manuals, application notes, "General Notes for Handling and Using Semiconductor Devices" in the reliability handbook, etc.), and ensure that usage conditions are within the ranges specified by Renesas Electronics with respect to maximum ratings, operating power supply voltage range, heat dissipation characteristics, installation, etc. Renesas Electronics disclaims any and all liability for any malfunctions, failure or accident arising out of the use of Renesas Electronics products outside of such specified ranges.

9. Although Renesas Electronics endeavors to improve the quality and reliability of Renesas Electronics products, semiconductor products have specific characteristics, such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Unless designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not subject to radiation resistance design. You are responsible for implementing safety measures to guard against the possibility of bodily injury, injury or damage caused by fire, and/or danger to the public in the event of a failure or malfunction of Renesas Electronics products, such as safety design for hardware and software, including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult and impractical, you are responsible for evaluating the safety of the final products or systems manufactured by you.
10. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. You are responsible for carefully and sufficiently investigating applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive, and using Renesas Electronics products in compliance with all these applicable laws and regulations. Renesas Electronics disclaims any and all liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
11. Renesas Electronics products and technologies shall not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations. You shall comply with any applicable export control laws and regulations promulgated and administered by the governments of any countries asserting jurisdiction over the parties or transactions.
12. It is the responsibility of the buyer or distributor of Renesas Electronics products, or any other party who distributes, disposes of, or otherwise sells or transfers the product to a third party, to notify such third party in advance of the contents and conditions set forth in this document.
13. This document shall not be reprinted, reproduced or duplicated in any form, in whole or in part, without prior written consent of Renesas Electronics.
14. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products.

(Note 1) "Renesas Electronics" as used in this document means Renesas Electronics Corporation and also includes its directly or indirectly controlled subsidiaries.

(Note 2) "Renesas Electronics product(s)" means any product developed or manufactured by or for Renesas Electronics.
